USER’S GUIDE

TBL TOOL DOCUMENTATION: DESIGN, MEASURES, AND SCORING
Triple Bottom Line Tool For Economic Development:

User’s Guide

Working Draft: Version 1.1

October 10, 2012

This project was funded by the US Economic Development Administration as part of Technical Report Award Number 99-07-13871.

The authors of this report are Dr. Janet Hammer, Dr. Gary Pivo, Dr. Ira Goldstein, and Maggie McCullough. Appreciation is given to the numerous reviewers who generously shared their time and insights. The authors are solely responsible for the report content and endorsement or approval by the reviewers and contributors or their organizations is not implied.

The Triple Bottom Line Tool can be accessed at http://tbltool.org/. This User’s Guide to the TBL Tool is a working document. Questions and comments about the TBL Tool or User’s Guide can be directed to Dr. Hammer at hammerj@pdx.edu.

TBL Tool Overview

Welcome to the Triple Bottom Line Tool User’s Guide. The Triple Bottom Line Tool (TBL Tool) is a web-based platform that helps investors, decision-makers, and economic development professionals enhance the performance of investments by better accounting for a broad array of economic, environmental, and social impacts of investment—what’s referred to as the triple bottom line or TBL.¹ This document provides an overview of the TBL Tool’s purpose, design process, and content. Details about the TBL Tool’s measures and scoring are provided, including why specific measures were chosen, how they are defined and scored, and what alternatives were considered.

Traditionally, economic development investment impact has been measured in jobs created and dollars leveraged. While important, these two measures do not provide a complete picture of the many significant impacts that investment can have. Investors and decision-makers are increasingly seeking ways to ensure that their economic development investments align with goals for social, environmental, and economic performance. Progress has been made on a number of fronts (e.g., B Corp, GIIRS, IRIS and LEED)²; however, there is no common standard or framework to assess economic development investments with respect to triple bottom line goals. Responding to this gap, the U.S. Economic Development Administration (EDA) has funded the creation of an on-line tool to design and assess economic development investment for triple bottom line impact.

The TBL Tool can be used to design for better outcomes, decide between projects, or describe project impacts. It can facilitate more complete and robust accounting, align economic development investments with other community priorities, and help to ensure that scarce resources are used as efficiently, effectively, and strategically as possible. The TBL Tool is designed to be easy to use, and to respond to various sizes and types of communities and investments. The TBL Tool is useful to policymakers, investors, and economic development professionals and is relevant in the public, private, and non-profit sectors.

TBL Tool Development Process

The process for developing the TBL Tool has been rigorous, inclusive, transparent, and pragmatic. This section of the User’s Guide provides an overview of the TBL Tool development process, introduces the core project team, highlights engagement efforts, and explains how we identified the TBL Tool performance areas and measures.

¹ The triple bottom line (TBL) is a term that originated in the corporate sector and refers to the economic, environmental, and social value of an investment. John Elkington, a business consultant and author, is credited with coining the term. Other phrases used to capture this concept include “people, planet profit,” sustainability, and “three legs of the stool.”
² Companies may become certified B Corporations if they meet specific third party standards for social and environmental performance. In a number of states, companies may obtain legal status as a Benefit Corporation meaning they have certain obligations regarding purpose, accountability, and transparency. Benefit Corporations are not required to be certified. The Global Impact Investing Ratings System (GIIRS) provides third party ratings for the social and environmental impact of a company or fund. Impact Reporting and Investing Standards (IRIS) provides a common set of metrics for reporting financial, environmental, and social impact of an organization or product. Leadership in Energy and Environmental Design (LEED) provides third party certification for the built environment ranging from individual buildings to neighborhoods and communities.
Development Team
The project is led by Dr. Janet Hammer from Portland State University, in collaboration with Maggie McCullough from PolicyMap, Dr. Gary Pivo from the University of Arizona/Harvard University Responsible Property Investing Center, and Dr. Ira Goldstein from The Reinvestment Fund. Portland State University is known for its leadership in sustainability issues and its commitment to the motto, “Let knowledge serve the city.” PolicyMap is an award-winning on-line platform whose value is captured in their tag line – “Good Data, Smart Decisions.” The Reinvestment Fund is one of the country’s oldest and most successful Community Development Financial Institutions. The Responsible Property Investing Center has developed industry-responsive TBL metrics for the built environment.

The TBL Tool has been developed in collaboration with many partners, including national advisors who provided review and feedback at strategic points during the processes as well as additional staff from Portland State University and PolicyMap. Acknowledgements are provided in Appendix One.

Engagement
To ensure that the TBL Tool is relevant and user-friendly, there have been a number of points of contact with economic development professionals and topic experts. Our engagement methods and objectives included the following:

Focus groups Seven focus groups were held between January and March 2011 with economic development professionals who are members of the International Economic Development Council (IEDC) or the National Association of Development Organizations (NADO) in order to learn more about current decision-making practices and hear feedback on the draft tool design.

Interviews Five interviews were held with EDA regional staff in March 2011 to better understand current practice regarding triple bottom line in economic development.

Survey An on-line survey of approximately 500 economic development practitioners was conducted in April and May of 2011 to identify current investment practices and priorities.

Advisors Economic development practitioners and topic experts provided input on the TBL Tool development.

Testing Feedback on the Beta version of the TBL Tool is being collected via a user-friendly on-line survey, as well as through more extensive testing and collaborative discussion with a group of testing partners that represent diverse geographies and organizational type (e.g., public, private, and non-profit investors at local, regional, state, and national levels).

Defining TBL Economic Development
Triple bottom line economic development is defined as programs, policies, or activities designed to create or retain jobs and wealth that contribute to community well-being and sustainability over time.³

³ Our definition draws from the International Economic Development Council (IEDC) (http://www.iedconline.org/?p=FAQS), as well as such scholarship as Edward Blakely and Nancey Green Leigh’s Planning Local Economic Development, Fourth Edition (2010), Daphne Greenwood and Richard Holt’s Local Economic Development in the 21st Century: Quality of Life and Sustainability (2010) and Kent Portney’s Taking Sustainable Cities Seriously: Economic Development, the Environment, and Quality of Life in American Cities (2003). We use the term well-being to refer to overall health (e.g., physical, financial, emotional), and use the generally
This type of economic development strives for qualitative and quantitative improvements in the lives of individuals and communities. It is distinct from economic growth, which may or may not contribute to overall community well-being (e.g., quality of life, fiscal balance, human and environmental health).

The TBL Tool is designed to help optimize economic development investments for triple bottom line performance. To define what that is we analyzed existing community priorities, current research, and leading edge practice:

- Thirty-one comprehensive community indicator programs from a range of urban and rural communities across the U.S. were analyzed to ensure that the TBL Tool aligns with and supports common priorities defined at city, county, regional and state levels.
- More than forty existing assessment tools were reviewed to identify the common TBL themes that appear across a range of sectors including business (e.g., GRI and GIIRS), land use and real estate (e.g., LEED-ND, Sustainability Checklist), and infrastructure (e.g., GreenLITES).
- An extensive literature review using approximately fifty search term combinations in four academic databases was conducted to ensure that measures are consistent with current research.

Synthesizing the findings from these three reviews, we identified key priorities that economic development investment should align with and support: economic vitality, good governance, healthy people, strong social fabric, natural resource stewardship, and quality built environments. We then worked with our project advisors and topic experts to translate these priorities into triple bottom line goals, performance areas, and measures that can be considered when assessing economic development investment. Draft measures were sent to national project advisors for review in June 2011 with subsequent input and vetting over the summer. A two-day work session with a subset of national advisors was held in October 3rd and 4th 2011 in Portland, Oregon to finalize measures and TBL Tool design decisions.

Measures were defined by considering availability and quality of data, as well as responsiveness to the unique features of particular communities and projects. We reviewed evidence pertinent to each performance area to ensure that measures align with best available science. This research involved more than 300 search term combinations. We also reviewed standards, certifications, and best practices for relevance to TBL Tool (e.g., green building certification programs). This research included 200 search terms applied to a web-based search.

In defining the TBL Tool performance areas and measures we aimed to balance parsimony and ease of use, with comprehensiveness and accuracy. The goals, performance areas, and measures are summarized below in Table One and are detailed in the following sections. Additional information regarding the TBL Tool development process including the review of indicators, literature, and other tools can be found in Appendix Two.

Eighteen cases were compiled to help illustrate triple bottom line economic development in practice and identify lessons learned. The cases include review tools, comprehensive economic development strategies, and projects representing various types of ED (e.g., business development, infrastructure, institutions and services, manufacturing and industry, mixed use development, and culture, recreation, accepted definition of sustainability as meeting the needs of current generations without compromising future generations’ ability to meet their needs.
Using the TBL Tool

Effective application of the TBL Tool requires an understanding of its intended purpose and scoring framework. Resolution of these design issues was informed by input from the project core team, EDA staff, topic experts, and national advisors.

Intended Purpose

The TBL Tool is best viewed as a reconnaissance device that can help optimize investments for economic, environmental, and social impact. The TBL Tool can enhance the design and decision-making process to maximize impact and ensure that economic development investments align with and support overall community priorities.

The TBL Tool can be used in a number of ways. For example, it can be used to optimize project impact (design tool); it can be used to winnow or compare projects (decision tool); and it can be used to describe project impact (communication tool). The TBL Tool is supported with information that allows the user to explore why particular elements were selected, as well as examples or best practices for achieving better results. Thus, the TBL Tool can also be used to build understanding about economic development processes and impacts (education tool).

Scoring Framework

The TBL Tool applies a technique called multi-criteria decision analysis to assess how well an investment aligns with triple bottom line goals. Multi-criteria decision analysis (MCDA) allows items of interest that are measured in different ways to be considered together. For example, imagine you would like to select a product based on purchase price, maintenance costs, user interface, and environmental impact. Each of these criteria is measured in different ways. Multi-criteria decision analysis provides a way to sum up these “apples and oranges.” The following is a brief overview of the multi-criteria scoring system used for the TBL Tool.

Selecting Criteria

As described elsewhere, the criteria (measures) were selected based on their contribution to the concept of TBL economic development and availability of data. Following best practice for multi-criteria decision analysis (MCDA), the following considerations were also made: a) minimize the number of criteria used without ignoring valid concerns, b) avoid highly correlated criteria/double counting and c) avoid overweighting one dimension by using a similar number of indicators for each dimension or subtotaling each separately before computing final score.

Scoring Criteria

There are a number of ways to grade or score a measure and the same approach does not need to be used for each criteria. For example, one measure may be scored on a -3 to +3 scale and another on a 0 to 100 scale. When aggregating into a total score, however, the scores are converted or normalized into the same scale. A common method for doing so is to calculate relative distance from best to worst; for example, a score that is halfway between worst and best on any scale is reset to 50 on a scale of 0-100, putting all scores into “relative preference percent rank order.”
For example:

The TBL Tool normalizes all measures to a 0 to 100 scale. For example, a measure that considers the percent of employees with access to benefits will score on a continuous range of 0 to 100, a measure that considers implementation of green building practices will provide discrete score options of 0, 50, 75, 100 depending upon the rigor of documentation (e.g., third party certified), while a measure that offers a yes or no response (e.g., pro forma conducted) will provide a binary score option of 0 or 100.

In MCDA, weights may be assigned when clear preferences are known. For example, if there are three criteria (A, B, and C) and A is of greater importance to the decision-makers then the criteria may be weighted. Imagine there are two projects and Project One scored 8, 7, and 7 and Project Two scored 10, 6, 6 on criteria A, B, and C, respectively. If criteria A were weighted as two times more important, then the total scores for Projects One and Two would be 30 (16 + 7 + 7) and 32 (20 + 6 + 6), respectively, while unweighted they would both score 22. The most compelling case for weighting with respect to the triple bottom line pertains to natural capital impacts (i.e., depletion of basic ecosystem services without which life cannot continue), however, there is not sufficiently robust information with which to make such a determination with the TBL Tool. Thus, no weights are assigned.

Approaches to missing data in the TBL Tool vary depending upon what data is missing. In some cases, the goal and performance area scores can be calculated without including the measure. For example, if transit data is not available for the project location, the measure score is reported as NA and the performance area score is calculated without the measure score. In other instances, missing data is not allowed and the TBL Tool will not generate a summary report. This approach prevents someone from generating what appears to be a high score though without addressing many of the measures necessary to provide a reasonable assessment.

The TBL Tool was designed to be responsive to differences in project type and other contextual features. In project scoring this manifests in the form of bonuses, NAs, and FYIs. For example, if average project wages will be 120% or greater than county average wages receives a bonus point while a project without high wages is not penalized. This is because, while jobs with good wages and benefits are an important part of the triple bottom line, we recognize that it is usually better to have some jobs than no jobs at all.
If an item is not relevant to a specific project, it is not included in the score and is noted as "NA." For example, if the project includes housing there is a question about affordability and if the project does not include housing that question is skipped and is not used in the calculation of the project score. Other items are not included in the score but are presented as an ″FYI.″ For example, dollars leveraged is not part of the TBL Tool score because there is no researched-based rationale for suggesting that the performance of a project is affected by the amount of leveraged dollars. At the same time, this is important information that many investors want to see, so it is provided but is not included in the project score.

**Aggregating and Reporting Results**

The score for each of the three goals (economic vitality, natural resource stewardship, and community vitality) is calculated by taking the average of the goal’s performance area scores, and each performance area score is calculated by taking the average of its measure scores. Results are reported for each goal, performance area, and measure. The project summary report displays the project information along with the project score. This provides a quality check on data entry and quality (e.g., response entered correctly, data set accurate), and provides an opportunity to explore areas of strength or weakness.

A four-color legend is provided (green, blue, yellow, red) to help the user identify how well the project appears to align with triple bottom line goals. The TBL Tool includes information bubbles that provide a summary of why a measure is important and how the measure is scored. In addition, a due diligence report is generated noting items that should be confirmed (e.g., applicant claim regarding green building certification) or explored (e.g., project appears to be located in sensitive natural resource area).

**Appropriate Use of the TBL Tool Scores**

This version of the TBL Tool is best viewed as a design and decision aid that helps identify areas of potential concern and options for designing a project for optimum results. The results (scores) provide a general indication of the strength of a proposal. Given that the scores are based on user-defined information and national data sets, due diligence should be conducted to ensure that project information is accurate (e.g., claims are true, data is not missing or incorrect). For example, if green building practices are claimed, a follow-up to confirm the claim is in order. Similarly, a project located in an area identified as containing steep slopes will receive a cautionary score for that measure and follow-up can identify whether project placement presents a risk.

It would not be appropriate to suggest that a project with a score of 72 is better than a project that scored 70; it would be appropriate to say that the two projects scored similarly and that specific areas of strength or weakness may merit further examination. When differences in project scores are large – for example, one project score is 80 and another is 40 – it is appropriate to note that one project appears to be better aligned with TBL goals than another, and to identify where there may be opportunities to reconfigure the weaker proposal to better align with community priorities and, thus, achieve a higher score.

We caution against directly comparing project scores for a number of reasons. First, as noted above, the TBL Tool relies on user input and national data sets that require due diligence follow-up. This follow-up needs to be conducted before determining whether one project or another appears to better align with triple bottom line goals. Second, as noted above, because a measure is scored NA when data is not available (e.g., Walk Score does not cover the location), one project might have a lower overall score than another simply because the first received a low score for a measure while the second received an
NA (though might actually have a similar or worse performance for that measure). Third, for a number of measures, the TBL Tool identifies the presence of impact without attempting to arbitrate the magnitude or significance of the impact to the community. For example, in the Beta version of the TBL Tool, a multi-million dollar cultural facility and an interpretive exhibit for a trail would both receive a point for contribution to cultural or historic resources. The score simply notes whether a historic or cultural resource is being impacted and leaves it to the investor to determine the relative merit.

**Current Limitations**

The Beta version of the TBL Tool draws on location data, industry data, and user-defined project information to calculate a project score. The Beta version of the TBL Tool cannot assess investments that do not have a specific location or address (e.g., a citywide conservation program) because some measures are location based (e.g., proximity to sensitive natural resources, location in distressed area). The TBL Tool applies to both construction investments and non-construction investments (e.g., training program at a specific facility), as long as there is a project location. Application of the TBL Tool to investments that do not have a specific location or address is being considered for future versions.

The Beta version of the TBL Tool serves most of the fifty United States. At this time, the TBL Tool cannot be applied to the U.S. Territories due to data limitations. This includes Puerto Rico, Guam, the Marianas, the U.S. Virgin Islands, and American Samoa. There is interest in creating a version of the TBL Tool that would apply in these areas, as well as in non-U.S. locations.

**Areas We’re Keeping an Eye On**

Descriptions of each measure are provided in the following section, including information regarding why a measure was selected, alternatives considered, and potential caveats or limitations. There are a number of measures that we seek better options for, but for which there do not appear to be better alternatives at this time. While we are monitoring the accuracy and utility of all measures during Beta testing, there are a few items that we are paying particularly close attention to. These include:

- **Wages** – How often do users know the average wage for the direct jobs created and retained? Are county averages serving as a reasonable comparator for project average wages given that averages for labor shed/commute shed are not available by North American Industrial Classification System (NAICS)?
- **Benefits** – How often do users know the benefit information for direct jobs created and retained? Is there a more accurate or reasonable alternative to assess this important component of job quality?
- **Sensitive Natural Resources** – The TBL Tool draws on national data sets that meet federal mapping standards but may not align with the identified project boundaries. Due diligence and field surveys are recommended to confirm the project location relative to sensitive natural resources. There are known data limitations regarding flood zone data, wetlands data, forestland data, and prime farmland data. Further, it may be that the map units are too coarse or the subtleties of context too great for the existing sensitive natural resource scoring framework. For example, a mapping unit may contain steep slopes and, thus, trigger a low score even if the built portion of the project is not near the slopes of concern. In these instances, what might be a reasonable way to consider the presence of a potentially sensitive natural resource without inappropriately penalizing a project (e.g., include a question that confirms the accuracy of the map provided and change the score if appropriate).
• Location Accessibility – In the Beta version of the TBL Tool, transit accessibility is measured by using Transit Score, a national platform that rates how well a site is served by transit. Ideally, the location accessibility measure would note not only how well the site is served by transit (e.g., number and frequency of transit choices), but the percentage of workers in the area that can access the site by transit within a specific timeframe. While progress is being made to create such data sets, they are not currently available.

• NAICS Codes – Some of the TBL Tool measures are based on the proposed investment’s NAICS (industry) code. The TBL Tool is designed to handle up to five NAICS (industry types) for a proposed investment (e.g., a project with office, retail, restaurant, gym, social service, library). Key questions include: Are five NAICS options enough, how often are users unable to find a NAICS to fit the project, and are there any issues associated with the NAICS code changes made in 2012?

• Order of Magnitude – In order to respond to the unique context of a project and community, the TBL Tool does not attempt to determine the scale, quality, or value of an investment’s contribution for a number of the measures. For example, the user identifies whether the project will impact cultural or historic resources but the TBL Tool does not arbitrate how significant the impacts are. The preservation of a cultural district can receive the same score as the installation of an art piece or historical marker. Is it important to differentiate order of magnitude for these types of measures and, if so, is there a fair and reasonable way to do so?

• Applicability of TBL Tool Across Project Type, Size, and Location – The TBL Tool was designed to be responsive to context. A great deal of consideration was given to the applicability of measures to a range of investment type (e.g., infrastructure, business development, culture and tourism), location (e.g., rural, urban), and size (e.g., dollars, acres). Is the TBL Tool performing well in diverse conditions and what might be improved in that regard? Further, the Beta version of the TBL Tool considers impacts associated with investment location (e.g., sensitive natural resources, community distress). Is there a way to adapt the TBL Tool to accommodate investments that are not location based?

• Weighting – Weights have not been assigned to any performance areas or measures, however, implicit weighting occurs when the number of measures in a performance area varies. Measures that belong to a performance area with few other measures carry more weight when the average for the performance area is calculated. For example, if one performance area has 3 measures and another has 6 measures, the impact of a measure in the second is less than the impact of a measure in the first because it is averaged with five other measures rather than two. Consider the impact of a measure score of 10 when the other performance area scores are 2: If there are three measures in the performance area the average score is 4.7 (10, 2, 2), and if there are six measures in the performance area then the average score is 3.3 (10, 2, 2, 2, 2, 2). During Beta testing we will consider whether it makes sense to retain the grouping of measures by performance areas for scoring purposes.

• TBL Goals and Scoring – Economic, environmental, and social performance are inextricably linked, with most measures impacting more than one bottom line. For example, an investment in green building may result in energy cost savings, increased building value, higher occupant satisfaction and productivity, and fewer negative impacts on human and natural resource health. Thus, while the green building measure is located and scored in the natural resource goal area it actually impacts all three of the goal areas. These interconnections are not reflected in scoring frameworks that “bucket” various measures. Is it important to better reflect the contributions of specific measures to multiple bottom lines and, if so, how might the scoring be altered to accomplish this (e.g., provide a total project score and do not assign measures to specific goals and performance areas)?
TBL Tool Measures

The Beta version of the TBL Tool includes eight performance areas and fifty-seven measures. The measures are summarized in Table One by goal and performance area. Many of the measures compliment current EDA application requirements and should serve to assist potential applicants in compiling necessary information (Appendix Three). Measure scoring – including the use of bonus, FYI, and NA – is described in the Scoring Framework section above.

Table One: TBL Tool Goals, Performance Areas, Measures

<table>
<thead>
<tr>
<th>GOAL: ECONOMIC VITALITY</th>
<th>Investments promote regional economic strength and resilience, are fiscally sound, and provide access to good quality jobs.</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Quality Jobs</td>
<td></td>
</tr>
<tr>
<td>Relative Impact on Employment</td>
<td>Bonus for investments with relatively large or catalytic impact on employment in the area. Information on the number of direct jobs is provided but is not included in score because a) number of jobs does not capture relative scale (e.g., 10 jobs in a small town versus a big city) and b) absence of a suitable benchmark for scoring.</td>
</tr>
<tr>
<td>Direct Jobs</td>
<td>Provides, FYI, the number of direct jobs created and/or retained.</td>
</tr>
<tr>
<td>Direct Jobs – Good Wages and Benefits</td>
<td>Bonus if average annual wages for the project’s direct non-construction jobs are 120% or greater than area average annual wages. Considers percentage of employees covered by benefits (e.g., health insurance, retirement contribution, paid vacation and sick time).</td>
</tr>
<tr>
<td>Direct Jobs – Career Access and Advancement Opportunities</td>
<td>Considers presence of career training, hiring, and advancement programs for direct non-construction jobs.</td>

</table>
**GOAL: NATURAL RESOURCE STEWARDSHIP**  
Investments make efficient use of natural capital and ecosystem health is maintained or restored.

### 3. Industry Eco-efficiency of Production (resources consumed and emissions produced per job)

**Fossil Fuel Energy Use**  
Identifies sectors with relatively higher and lower energy use per job.

**Water Use**  
Identifies sectors with relatively higher and lower water use per job.

**Solid Waste**  
Identifies sectors with relatively higher and lower solid waste per job.

**Ozone Depletion**  
Identifies sectors with relatively higher and lower ozone depletion per job.

**Acidification**  
Identifies sectors with relatively higher and lower acidification impact per job.

**Photochemical Smog**  
Identifies sectors with relatively higher and lower photochemical smog impact per job.

**Eutrophication**  
Identifies sectors with relatively higher and lower eutrophication per job.

**Ecotoxicity**  
Identifies sectors with relatively higher and lower ecotoxic emissions per job.

**Greenhouse Gases**  
Identifies sectors with relatively higher and lower greenhouse gas emissions per job.

### 4. Green Design and Construction

**Green Building/Construction**  
Considers implementation of green standards, certifications, and practices.

**Adaptive Reuse**  
Bonus to projects that reuse existing structures.

**Sustainable Site Design**  
Considers implementation of sustainable site design standards, certifications, and practices.

**Remediated or Restored Lands**  
Bonus to projects that contribute to remediation of brownfield or habitat restoration.

**Avoidance of Sensitive Natural Resources**  
Considers location in or near sensitive areas (floodplain, critical habitat, steep slopes, prime farmland, wetlands, water bodies, protected areas, forestland).

### 5. Green Operations

**Energy from Renewable Sources**  
Considers percentage of project energy derived from renewable energy sources.

**Energy Management**  
Considers whether facility performance is monitored through participation in Energy Star management program.

**Automobile Trip Reduction Strategies**  
Considers implementation of automobile trip reduction strategies (e.g., telecommuting, transit passes, shuttles).

**Tenant Environmental Incentives**  
Considers incentivizing of tenant implementation of green operation and management practices.

**Water Use Lower Than Industry Norms**  
Bonus for conservation practices that lead to lower water use relative to industry.

**Emissions Lower Than Industry Norms**  
Bonus for practices that lead to lower toxic emissions relative to industry.

**Industry Best Practices**  
Bonus to projects that adopt industry best environmental standards and/or certifications.

**Green Products and Services**  
Bonus to projects with jobs created or retained that pertain to green products and services.
## GOAL: COMMUNITY WELL-BEING
Investments preserve or enhance unique culture, promote health and opportunity, and cultivate distinctive and well-functioning communities in which to work and live.

### 6. Placemaking and Accessibility

<table>

</table>

### Cultural and Historic Resources

- Considers whether project preserves, enhances, or diminishes historically or culturally significant practices, structures, facilities, or districts.

### Public Spaces

- Considers whether project creates, enhances, or diminishes public space.

### Walkability of Project Location

- Considers walkability of project location.

### Transit Accessibility of Project Location

- Considers transit accessibility of project location.

### Project Increases Walking, Biking, or Transit Options

- Bonus to projects that increase walking, biking, or transit options in the area.

### Location in High Need Areas

- Bonus to projects located in an area defined as distressed or severely distressed.

### No Net Loss of Affordable Housing

- Where restricted affordable housing is present, considers one-for-one replacement of units.

### Housing Affordability

- For projects that include housing, considers creation of affordable housing in excess of any one-for-one replacement.

### 7. Environmental Health

<table>

### Prevention and Mitigation of Business and/or Resident Relocation

- Considers whether residents or businesses will be relocated as a result of the project and, if so, presence of an appropriate relocation strategy.

### Prevention and Mitigation of Business and/or Resident Displacement

- Considers whether residents or businesses will be displaced as a result of the project and, if so, presence of an appropriate strategy to prevent and mitigate displacement.

### Anti-poaching

- Considers whether project encourages relocation of existing jobs away from other communities.
The following section provides detailed scoring information for the performance areas and measures for each of the three TBL Tool goals (economic vitality, natural resource stewardship, community well-being). The information provided includes why a specific performance area is important, what measures were selected to operationalize the performance area, the measure formula and scoring, any data limits or caveats, and sources of additional information if appropriate.

**Goal: Economic Vitality**

Economic vitality refers to a system of production, distribution, and consumption that generates and retains wealth in a community and successfully weathers disruptions or changes to the system. In the Beta version of the TBL Tool, the Economic Vitality goal is comprised of two performance areas: Quality Jobs – which considers economic impact at the individual level (e.g., wages, benefits, and career opportunities), and Sound Investment – which considers economic impact at the project and community level (e.g., fiscal responsibility and support for regional economic strength and resilience). A project’s score for the Economic Vitality goal is calculated by averaging its scores for the Quality Jobs and Sound Investment performance areas, as described below.

The following information details why each performance area is important, the measures selected to operationalize the performance area, the measure formulas and scoring, and any data limits or caveats.

**Performance Area: Quality Jobs**

*Why Does This Matter?*

In modern economies, most people must earn income to meet basic needs. Research demonstrates that health and well-being are strongly correlated with income. Further, well-paying jobs contribute to community economic vitality by stimulating the economy, generating tax revenues, and reducing the need for public assistance. Reward for work is a basic tenet of our society, with the expectation that full-time employment is sufficient to meet basic needs.

Along with good wages, employee benefits are an important aspect of job quality. Benefits such as health insurance, sick days and personal days, vacation days, and retirement contributions can foster workforce health and productivity, reduce financial burdens on taxpayers, and contribute to the attraction and retention of skilled workers. When access to employment opportunity is not available to members of society, the result is lost potential and added costs to individuals, families, businesses, and society. Thus, triple bottom line economic development aims to create and retain quality jobs that provide fair compensation for work and opportunities for employment access and advancement.

*What Do We Want To Know?*

- Is the impact on employment large or catalytic for the investment benefit area?
- Do the jobs created and retained pay well and provide benefits?
- Are pathways to opportunity being created (e.g., employment access and advancement)?

*What Measures Were Selected to Operationalize This Performance Area?*

The Quality Jobs performance area measures are as follows:

- Relative Impact on Employment
- Direct Jobs
- Direct Jobs – Good Wages and Benefits
- Direct Jobs – Career Access and Advancement Opportunities
• Construction Jobs
• Construction Jobs – Good Wages and Benefits
• Construction Jobs – Career Access and Advancement Opportunities

The Quality Jobs performance area score is calculated by averaging the scores for five of the seven measures: Relative Impact on Employment, Direct Jobs’ Wages and Benefits, Direct Jobs’ Career Access and Advancement Opportunities, Construction Jobs’ Wages and Benefits, and Construction Jobs’ Career Access and Advancement Opportunities. Two other measures – Direct Jobs and Construction Jobs – are not included in the score as explained below.

1. Relative Impact on Employment

This measure considers the relative impact of jobs created or retained and provides a bonus score to investments that have a significant impact on employment in the area or are catalytic (e.g., may not generate a lot of direct jobs but is an essential component for further growth). This measure recognizes that the relative impact of jobs created or retained varies with context. For example, the creation or retention of ten jobs in a small town of 500 people might have a significant impact on the town while the creation or retention of ten jobs in a city of 500,000 people may have less impact on the city.

Further, an investment may produce or retain a relatively small number of jobs though the investment is responsible for generating many more. For example, an infrastructure investment that supports expansion, refurbishment of a historic theater than catalyzes investment in an entertainment district, or creation of a maritime center whose job impact is greatest through tourism and an expanded customer base for maritime related businesses in the area.

Measure Formula and Scoring
The TBL Tool asks whether the number of jobs created or retained will distinguish the project as a major employer in the area or have a particularly catalytic impact on employment in the area. An example of a catalytic project is an arts center that does not create a lot of direct jobs but is a destination of renown that greatly supports the creation of jobs in tourism and arts related businesses. Another example might be a small technical center that provides critical assistance to farmers throughout the region.

If the response to this measure is Yes (relatively large or uniquely catalytic impact on employment), a bonus score of 100 is earned. If the response is No (not a large or uniquely catalytic impact on employment), no bonus score is earned. A text box to provide information to support the claim is provided. The measure is scored as a bonus point so that projects with large relative impact are rewarded but other projects are not penalized.

Caveats
Evidence to support the claim should be submitted.

Alternatives Considered
• Jobs created as a percent of investment benefit area unemployment (user estimate of direct non-construction jobs created and retained/current unemployment data) was not applied for a number of reasons: 1) potential correlation or redundancy with the measure regarding investment location in an area of high need (which considers unemployment), 2) inability to account for catalytic impact, 3) lack of a standard for scoring (e.g., is a “good” or “large” impact .2% of employment, 2%, or 20%?), and 4) data issues (lack of data for area of interest).
• Percent increase in jobs (direct non-construction jobs created and retained/current employment in the investment benefit area), was not applied for a number of reasons: 1) potential correlation or
redundancy with the measure regarding investment location in an area of high need (which considers unemployment), 2) inability to account for catalytic impact, 3) lack of a standard for scoring (e.g., is a “good” or “large” impact measured as percent increase in jobs), and 4) data issues (lack of data for area of interest).

- Scoring based on whether the project creates more or less jobs than an average economic development project of that type and location was not applied because benchmark information is not available. In theory, it might be possible to identify average jobs created for economic development investments in rural communities and urban communities (infrastructure and non-infrastructure capital projects) and then score the proposed project based upon whether the direct jobs created are significantly above or below the average for the project type and location (rural or urban). Scoring could then be based on standard deviation from mean or percent greater than average. This information is not currently available and, thus, this alternative was not feasible for the Beta version of the TBL Tool.
- Scoring based on the estimated annual wage bill for the project as a percent of the total county wage bill was not selected because of data quality concerns as well as a lack of standard for scoring.

2. Direct Jobs

This measure considers the number of direct non-construction jobs created or retained and provides the information as an “FYI.” This measure recognizes that the impact of jobs created or retained varies with context. For example ten jobs in a small town of 500 might have a significant impact on the town, while ten jobs in a city of 500,000 likely has less impact on the city.

Measure Formula and Scoring

The number of direct jobs created and/or retained when the project is complete is entered for each of the project industries. Up to five industries may be identified for a project. If the project includes more than five industries, the top five with respect to job creation and retention should be entered. The number of direct jobs created and/or retained includes part-time and seasonal employees and the figure is entered as FTE (full-time equivalents), which is based on a 40 hour per week workload (2080 hours per year). An employee working 20 hours per week is considered .50 FTE, while two employees each working 20 hours per week equal 1.0 FTE. Construction jobs are not entered here as they are counted elsewhere in the TBL Tool. Jobs performed by independent contractors can be included in the jobs figure and should be noted in the documentation.

Information regarding direct permanent job creation and retention is reported in order to provide a sense of expected impact. The information is not included in the project’s TBL score because there is no standard for defining a “good” or “bad” number of jobs created and retained.

Caveats

Job creation estimates require careful attention, as the figures may include overly optimistic estimates and/or may include jobs that are merely relocated from another area and do not represent net job growth. Evidence to support the claim of jobs created and/or retained should be provided.

The selected timeframe for estimated number of jobs created and/or retained is at the time of project completion because longer time horizons are too uncertain and discounting would be problematic. Care should be given to ensure that the appropriate time horizon was used for the calculation.
Alternatives Considered

The following options were considered to provide a “check” on, or alternative to, user estimates of employment:

- Land Use Employment Intensity Benchmarks – Estimates of average employees per square foot per sector could be provided as a means to confirm whether the user’s job estimate appears reasonable given industry averages (i.e., compare the number of employees per square foot for the project industry with the industry average). This option was not selected because the quality of the data is not sufficiently strong to use for scoring. Additional information regarding the use of nonresidential multipliers can be found in the following:

- NAICS averages – The U.S. Census provides estimates of the number of employees by firm size by NAICS and state (i.e., percentage of firms with 20+, 100+, and 500+ employees). For example, in Oregon 27% of manufacturing firms have 20 or more employees, 10.7% have 100 or more, and 5.3% have 500 or more ([http://www.census.gov/epcd/susb/latest/or/OR31.HTM](http://www.census.gov/epcd/susb/latest/or/OR31.HTM)). A comparison of the estimated number of jobs created and/or retained could be made to the industry average for the state. This option was not selected because the range is so large as to preclude meaningful comparison. The URL could be provided with a note stating something like, “To confirm whether your estimate is on par with industry averages for your state, visit [URL].”

- Jobs Per Dollar Invested – Calculating job creation and retention relative to the investment provides some perspective on the efficiency with which jobs are being created. For example, if one investment of $100,000 created 10 jobs and another investment of $100,000 created 5 jobs, the dollars invested per job would be $10k and $20k, respectively. All other things being equal, the first project could be favored because it is more efficiently creating jobs. By focusing on returns per dollar invested rather than total jobs created, projects of various sizes may be compared more equitably and effectively. At the same time, job creation that is relatively more expensive may be associated with an important feature such as higher paying jobs, catalytic investment, or creation of social and economic benefit through work with special populations (e.g., workforce training, prison re-entry, at risk youth). This option was not selected because there is not a reasonable standard for scoring a project based on the number of jobs created per dollar invested.

- Total Jobs – Total job creation and retention considers direct, indirect, and induced jobs. Direct jobs are those specifically tied to the project (e.g., employees at the manufacturing plant), indirect jobs are those that result from the business (e.g., suppliers to the manufacturing plant), and induced jobs are those that result from the spending attributable to the direct and indirect job creation (e.g., employees at both manufacturing plant and supplier spend money at grocery store). The total jobs figure is important to know, but is difficult to estimate. The two main options for incorporating multipliers into the TBL Tool were to use FedFit (a free fiscal impact tool developed by the Federal Reserve System) or fee for use impact tools such RIMS, IMPLAN, or Redyn. FedFit uses conservative

---

multipliers based on the area population (e.g., 1.05 for county populations 0 to 10,000, 1.35 for county populations 35,000 to 50,000, and 2.00 for county populations 200,000 and above). This option was not selected because the estimates were seen as too coarse for the TBL Tool and problematic given the relative advantage accorded to urban over rural projects. The commercially available options were not viable for the Beta version (e.g., there is not a national data set covering a range of investment and community types that can quickly or inexpensively be integrated with the TBL Tool). Given the absence of a reasonable data source, this measure was not included in the Beta version of the TBL Tool. It is approximated in the measure that considers whether the impact on employment will be large or catalytic for the area.

3. Direct Jobs – Good Wages and Benefits

This measure considers whether the direct jobs created or retained provide good wages and benefits.

Measure Formula and Scoring
This measure is comprised of three sub-measures: greater than average wages, provision of benefits, and tenant incentives for provision of employee benefits.

a) Average Project Wage 120% or Greater Than County Average Wage
This sub-measure compares the project average wages to county average wages and assigns a bonus point if the project wages are 120% or greater than county average. The calculation is made with the user defined average project wages or, if unavailable, the NAICS defined average project wage in the county. Average wages per NAICS are defined using the Bureau of Labor Statistics (BLS) Quarterly Census of Employment and Wages 2010 data (http://data.bls.gov/pdq/querytool.jsp?survey=en). Multiple NAICS are handled with weighting. For example, if the project includes three industries (A, B, C) and the industries provide 25%, 25%, and 50% of the jobs created and retained, respectively, then the average wage calculation is weighted accordingly (.25*average wage in A + .25*average wage in B + .50*average wage in C).

Bonus points are provided if the investment industry or industries pay higher than average wages for the area. There is no penalty if the project does not meet this standard because, it is generally better to generate some wages than none (e.g., taking some lower paying tourism jobs over no jobs at all). Also, the measure score is based on county and industry averages that may be too broad to accurately describe the project. Thus, while the triple bottom line is defined as having good wages, projects do not lose points if the wages are not above average.

Caveats
One caveat to the county average wage approach is that if a project will provide higher than average wages for the investment area but those wages don’t show up as higher than average for the county, then the benefit may be underrepresented. Imagine that the average wage in the county is $35,000 (tool data) and in the investment area is $25,000 (which the tool does not know) and a project is proposed that will pay at or close to its NAICS average county wage of $30,000. Using county averages, the TBL Tool will identify the proposed project as providing lower than average wages, yet in reality the project is providing higher than average wages in the benefit area. Counties are quite large in some rural areas and the county average may mask low wages where the project is located. However, since
no negative points are assigned for below average scores the worse case scenario is that a bonus point is missed.

Another caveat pertains to the fact that the average wages per NAICS are defined using the U.S. Department of Labor Bureau of Labor Statistics (BLS) Quarterly Census of Employment and Wages 2010 data (http://data.bls.gov/pdq/querytool.jsp?survey=en) and that data is not automatically updated in the TBL Tool. Though relative positions are not likely to change dramatically over time, the accuracy of the estimate will be compromised if there are major shifts in the mix of industries and wages in the county or in average wages for the project industries. This data set should be updated periodically.

Alternatives Considered
Alternatives for operationalizing “good wages” included the following:

• The BLS Occupational Employment Statistics Query System’s average wages for occupations by NAICS by area (state, county, metro/nonmetro) would provide more precise information than average wage per NAICS, however, use of this data would require the user to know how many jobs are being created in each occupation type for each NAICS and this was deemed to be an unreasonable expectation.

• Labor market areas (LMAs) or commute patterns were suggested as a preferred alternative for calculating the investment benefit area. However, the data that the TBL Tool needs for these measures do not exist for LMAs or commute zones. While the Local Area Unemployment Statistics (LAUS) program provides monthly and annual estimates for employment, the information does not include average wage by NAICS (needed for the TBL Tool’s calculations). Further, there may be data issues at small geographic areas where the figures are estimates and data currency can be lagging.

• The project average wage compared to family living wage for the area or percent of project jobs paying a living wage was considered but not applied due to concerns about user ability to know the project average wages, as well as concerns about data shelf life (e.g., will the data set be updated and, if so, how frequently). Information about the Living Wage Calculator can be found at http://www.livingwage.geog.psu.edu/. This calculator provides information at the county and place level by state.

b) Percent of Direct Jobs that Provide Good Quality Benefits to Employees
This sub-measure considers the percentage of direct employees of the completed project that are expected to receive good quality benefits. Good quality benefits refer to the type of benefits (e.g., health coverage for employee and family, sick days and personal days, vacation days, retirement), as well as the accessibility and affordability of the coverage (e.g., employee contributions, co-pays). The TBL Tool asks: What percent of the direct jobs created and/or retained do you anticipate will provide good quality employee benefits (e.g., affordable health insurance, sick days, vacation days, and retirement benefits)? The higher the percentage of covered employees the better the project’s score.

5 The Bureau of Labor Statistics’ general definition for a labor market area (LMA) is an economically integrated area within which individuals can reside and find employment within a reasonable distance or can readily change jobs without changing their place of residence. LMAs include both the metropolitan and micropolitan areas and are redesignated after each decennial census. Currently there are 2,368 LMAs. LMAs exhaust the geography of the United States and Puerto Rico, with the exceptions of Kalawao County, Hawaii, and 18 isolated cities and towns in New England (http://www.bls.gov/lau/laufaq.htm#Q06).
Caveats
One caveat is that while benefits are an important part of job quality, benefit information may not be readily available during the planning phases of a project. We are monitoring this measure closely during Beta testing.

Another caveat is that user’s may provide overly generous estimates regarding the amount and/or quality of benefit provided. Evidence to support the claims regarding benefits should be provided. In particular, affordability and quality of benefits should be considered along with eligibility (e.g., employee may be eligible but elect not to enroll due to high premiums or co-pays, or plan may be have low coverage).

Finally, this measure may need to be revisited pending changes to the national system of health coverage.

Alternatives Considered
Background information regarding the current status of benefits programs was conducted to inform the design of this measure. Research reviewed includes the National Compensation Survey (NCS) produced by the U.S. Department of Labor’s Bureau of Labor Statistics (http://www.bls.gov/ncs/); the Employer Health Benefits Survey conducted by the Kaiser Family Foundation and the Health Research and Educational Trust (http://ehbs.kff.org/); and the U.S. Department of Health and Human Services Medical Expenditure Panel Survey (http://meps.ahrq.gov/mepsweb/).

Initially, the Beta version of the TBL Tool was designed to consider the presence or absence of six types of benefits: percent of full time (FT) employees eligible for employer based health insurance, percent of part time (PT) employees eligible for employer based health insurance, percent of FT employees with eligibility for health insurance benefits for family members or domestic partners, percent of PT employees with eligibility for health insurance benefits for family members or domestic partners, health insurance plan quality, employer provision of paid sick days/personal days, employer provision of paid vacation and holiday days, employer contribution to retirement contribution plan/fund, and lease incentives for tenant provision of employee benefits. Scoring options considered included a) score equals percent of employees covered, b) score is based on performance relative to industry standard for the firm (e.g., national firm with thousands of employees will be subject to different expectations than a mom and pop shop, per national data on average benefits by firm size and type). These options were not implemented due to concerns about users’ access to benefit information in the reconnaissance or scoping phase – particularly for mixed-use projects and multiple tenant projects. Other quality of life benefits such as employer assistance for childcare, subsidized commuting, flex time were considered but were not incorporated at this time because the current rates of coverage are low (approximately 5% to 15% depending upon the benefit) and, thus, are not considered to be core to the definition of quality jobs. These items could be incorporated as a bonus point in future versions.

c) Incentives for Tenant Provision of Employee Benefits
In many instances, direct permanent jobs are created by a tenant at the project location rather than directly by the facility owner (e.g., owner of office building or shopping center). In these instances, while the project owners do not control the amount or type of employee benefits provided, they may provide incentives to tenants to encourage the provision of quality benefit programs. A bonus point is provided to projects with tenants when incentives are provided for tenant provision of benefits. If tenant incentives are not offered or if this information is not known, there is no impact on the project score.
Caveats
Evidence to support the claims regarding benefits should be provided and the strength and effectiveness of the incentive program considered.

4. Direct Jobs – Career Access and Advancement Opportunities

This measure considers the availability of career access and advancement opportunities that allow traditionally disadvantaged and underutilized members of society to build skills and contribute productively to society. Depending upon the community, these populations may include people of color, veterans, disabled individuals, women, and individuals re-entering society from the justice system. A number of strategies, if well designed and executed, can positively address barriers to employment entry and advancement.

Measure Formula and Scoring
This measure is comprised of four sub-measures that pertain to career access and advancement: hiring goals and performance monitoring; recruitment, training, and placement partnership; continuing education incentives; and partnership with underrepresented businesses. The score for this measure is calculated by taking the average of the four sub-measure scores, as described below.

a) Hiring Goals and Performance Monitoring
Hiring goals and performance monitoring can facilitate improvements in employment access and advancement by defining desired outcomes and tracking progress. Hiring goals should be defined with relevant community and agency input in order to ensure that they respond to the unique context of the place and project.

This sub-measure considers whether there will be agreements to collaborate with relevant workforce development and/or community-based organizations to define hiring targets appropriate to the area’s population and monitor performance (i.e., tracking baseline information, effort, requests and considerations, and results). Depending upon community context, target populations could include low-income residents, women, people of color, veterans, disabled individuals, or formerly incarcerated individuals. A range of strategies may be applied, including first source hiring agreements that provide target populations with effective notice of available positions along with exclusive consideration for a specific time period prior to open hiring. The parties to the agreement may vary with context and could include, for example, the developer and a community group or funder.

A project earns 100 points if binding agreements will be in place, 50 points if non-binding agreements will be in place, and 0 points if no agreement will be in place. Additional points are provided for the presence of binding agreements because they provide a higher degree of accountability.

Caveats
Evidence to support the claims regarding hiring goals and performance monitoring should be submitted and the likely effectiveness of the strategies considered.

b) Recruitment, Training, and Placement Partnership
Improvements in employment access and advancement are facilitated when appropriate recruitment, training, and placement activities are in place. Outreach, intake, screening, and referral are more likely to be effective if they are tailored to the target audience and delivered through an organization with a
proven track record that demonstrates they have the trust and skills necessary to successfully work with the target population.

This sub-measure considers whether agreements will be in place to partner with relevant community-based and/or public organizations to conduct recruitment, training, and placement appropriate to the defined target populations (e.g., cultural competency, success training and placing traditionally disadvantaged or underutilized populations). A project earns 100 points if binding agreements will be in place, 50 points if non-binding agreements will be in place, and 0 points if no agreement will be in place. Additional points are provided for the presence of binding agreements because this provides a higher degree of accountability.

Caveats
Evidence to support the claims regarding recruitment, training, and placement partnership should be submitted and the likely effectiveness of the strategies considered.

c) Continuing Education Investments
Career development requires both access and advancement opportunities. Investments in continuing education help individuals build skills necessary for advancement while increasing their contribution to organizational productivity and competitiveness.

This sub-measure considers whether agreements will be in place to provide staff development and training. Examples of continuing education investments include partnerships with higher education institutions to facilitate skills development, on-going skills training on the job, and contributions toward continuing education (e.g., workshops, seminars, courses). A project earns 100 points if binding agreements will be in place, 50 points if non-binding agreements will be in place, and 0 points if no agreement will be in place. Additional points are provided for the presence of binding agreements because this provides a higher degree of accountability.

Caveats
Evidence to support the claims regarding continuing education investment should be submitted and the likely effectiveness of the strategies considered.

d) Partnership with Underrepresented Businesses
The opportunity to start and grow a successful business may be limited by exclusion from networks and capital necessary to compete. This measure aims to ensure that entrepreneurial talent can thrive and that diverse community members can successfully compete for business. Expanding business opportunity to underrepresented populations requires more than posting a public notice. Successful strategies are tailored to the community while building on proven programs to utilize, mentor, contract with, or partner with underutilized businesses.

This sub-measure considers whether agreements will be in place to utilize, mentor, or partner with underutilized businesses. A project earns 100 points if binding agreements will be in place, 50 points if non-binding agreements will be in place, and 0 points if no agreement will be in place. Additional points are provided for the presence of binding agreements because this provides a higher degree of accountability.
Caveats
Evidence to support the claims regarding partnership with underrepresented businesses should be submitted and the likely effectiveness of the strategies considered.

5. Construction Jobs

Information regarding construction jobs is reported in order to provide a sense of expected impact. The information is not included in the project’s TBL score because there is no standard for defining a “good” or “bad” number of jobs created and retained.

Measure Formula and Scoring
The number of direct construction labor hours is entered. Construction jobs reported as full-time equivalent (FTE) can be converted by multiplying the FTE by 2,080 (full time hours per year). For example, 50 FTE construction jobs that will last one year are equal to 104,000 construction hours.

Caveats
Evidence to support the claim should be available.

6. Construction Jobs – Good Wages and Benefits

This measure considers whether the project’s construction jobs provide good wages and benefits.

Measure Formula and Scoring
The score for this measure is computed by calculating the average of the five sub-measures described below: employee classification, wages, health insurance, retirement benefits, OSHA compliant training, and Project Labor Agreements.

a) Proper Classification and Availability of Certified Payroll Records
Proper classification of workers as employees promotes fair competition and ensures that payroll taxes, worker’s compensation and other state- and federally-required funds are paid. When workers are misclassified as independent contractors rather than employees, contractors can unfairly compete by producing low bids achieved by passing costs on to workers and society at large. Making certified payroll records available is an important mechanism for demonstrating that workers are not misclassified as independent contractors or improperly paid.

This sub-measure considers whether workers will be properly classified as employees and certified payroll records are available to a public entity or advisory body. A project earns 100 points if a binding agreement will be in place and 0 points if no agreement will be in place.

Caveats
Evidence to support the claims classification and payroll records should be made available.

b) Prevailing Wages or Like Pay
Prevailing wage standards establish a baseline for wages and benefits in construction that are unique to specific geographic locations. Prevailing wage is typically determined by conducting a survey of contractors and is usually set as either the median or modal package of wages and benefits. Prevailing
wage requirements help reduce unfair bidding based on undercutting of standard wage and benefit packages in the region.

This sub-measure considers whether there will be a legally binding agreement to pay state defined prevailing wage rates for the trade or, where appropriate, "like pay" for the trade in the benefit area. Like pay refers to the average pay for the trade in the project area and may be an appropriate substitute for prevailing wage if the survey area establishing prevailing wage does not adequately reflect the project context (e.g., a rural project with wages set at a metro level). A project earns 100 points if a binding agreement will be in place and 0 points if no agreement will be in place.

Caveats
Evidence to support the prevailing wage or like pay claims should be available.

c) Health Benefits
Health benefits may be delivered through direct coverage of the employee by the employer (e.g., health insurance), coverage of the employee through employer contribution to a trade association (e.g., payment into benefit program offered by trade association), or as a supplemental or discretionary benefit (e.g., payments to health savings account, extra pay in lieu of coverage).

This sub-measure considers whether the project will include a legally binding agreement to provide health insurance benefit options to construction employees. A project earns 100 points if a binding agreement will be in place and 0 points if no agreement will be in place.

Caveats
Evidence to support the health benefit claims should be made available.

d) Retirement Benefits
Retirement benefits may be delivered through direct coverage of the employee by the employer (e.g., health insurance), coverage of the employee through employer contribution to a trade association (e.g., payment into benefit program offered by trade association), or as a supplemental or discretionary benefit (e.g., extra pay in lieu of coverage).

This sub-measure considers whether the project will include a legally binding agreement to provide retirement benefit options to construction employees. A project earns 100 points if a binding agreement will be in place and 0 points if no agreement will be in place.

Caveats
Evidence to support the retirement benefit claims should be made available.

e) Safety Training
Safety training in compliance with U.S. Department of Labor Occupational Health and Safety Administration (OSHA) is standard practice for a high-quality business. Workers who go through registered apprenticeship programs typically receive this training, which is designed to increase safety on the job and decrease work-related injuries and fatalities.

This sub-measure considers whether the project will include a legally binding agreement to ensure that all workers have participated in OSHA compliant 10-hour safety training, and that supervisors have
received the OSHA compliant 30-hour training. A project earns 100 points if a binding agreement will be in place and 0 points if no agreement will be in place.

Caveats
Evidence to support the safety training claims should be made available.

f) Project Labor Agreement
Project labor agreements establish key labor and management terms for a specific project. In general, project labor agreements (PLAs) address wages, hours, working conditions and procedures for resolving disputes, including agreements that restrict strikes or lock-outs. PLAs create a comprehensive framework that sets the terms for a project and requires all contractors and sub-contractors on the project to comply with the standards. The PLA can be inclusive of union and non-union workers. Responsible contracting standards may address issues such as wages and benefits, however, that is not always the case. PLAs are distinctive because they are established and implemented in consultation with worker organizations. This helps to ensure that workers’ perspectives are considered and provides standing to verify and enforce agreements. Executive Order 13502, signed in February 2009, encourages federal agencies to consider, on a case-by-case basis, whether to require a PLA on construction projects where the total cost to the federal government exceeds $25 million.

This sub-measure considers whether a project labor agreement is in place. For projects whose total cost is less than $10 million, a project earns 100 bonus points if a project labor agreement will be in place and 0 bonus points if no agreement will be in place (total score not affected if no PLA will be in place). For projects whose total costs are $10 million or more, 100 points are earned if a project labor agreement will be in place and 0 points are earned if no agreement will be in place. The sub-measure occurs as a bonus point for projects whose total cost is less than $10 million in recognition of the fact that such agreements more typically apply to projects of larger scale.

Caveats
Evidence to support the claim should be made available. Consideration should be given to the representativeness of the stakeholders involved, the quality of the agreement, and the strength of implementation provisions.

The appropriateness of the measure’s $10 million threshold should be considered during Beta testing.

Additional Information
Robust research regarding various types of PLAs and their impacts remains slim, however, the following resources may be useful:

7. Construction Jobs – Career Access and Opportunity

This measure considers the availability of construction career access and advancement opportunities that allow traditionally disadvantaged and underutilized members of society to build skills and contribute productively to society. Depending upon the community, these populations may include
people of color, veterans, disabled individuals, women, low income populations, or individuals re-entering society from the justice system. A number of strategies, if well designed and executed, can positively address barriers to employment entry and advancement.

**Measure Formula and Scoring**

This measure considers the presence or absence of five construction career access and advancement strategies: registered apprentice or training program; apprentice utilization; non-apprentice hiring goals; apprentice hiring goals; and utilization of underrepresented business. The score for this measure is calculated by taking the average of the five sub-measure scores, which are detailed below.

**a) Registered Apprentice or Training Program**

Apprenticeship programs are essential for building workforce skills and capacity. Registered apprenticeship programs are regulated by federal and state governments and are required to meet industry standards for graduating workers who can obtain employment in their field of training. Not all apprenticeship programs are registered, so contractors should provide documentation that they participate in a recognized program.

This sub-measure considers whether the contractor will be a registered apprentice program or training participant. A project earns 100 points if they will be and 0 points are earned if they will not be. The sub-measure is not applied if the investment does not include any construction activity.

*Caveats*

Evidence to support the claim should be made available.

**b) Apprentice Utilization**

Apprenticeship training programs typically require a combination of classroom and on-the-job training. Contractors need to hire apprentices so that apprentices receive the experience necessary to graduate and move into full employment. At the same time, apprentices are paid less than the journeyman wage rate: in order to ensure quality performance and prevent labor abuses, federal and state regulations specify maximum apprentice utilization.

This sub-measure considers whether a binding agreement will be in place to utilize apprentices to the maximum ratios allowed by state or federal regulations. A project earns 100 points if there will be such an agreement and 0 points if there will not be. The sub-measure is not applied if an investment does not include any construction activity.

*Caveats*

Evidence to support the claim should be made available.

**c) Equity and Opportunity Apprentice Hiring Goals**

Commitments to hire apprentices from traditionally disadvantaged and underutilized populations help to facilitate access to construction trade employment. Hiring goals should be defined with relevant community and agency input in order to ensure they respond to the unique context of the community and project. Collaboration is important for ensuring that goals reflect the needs of the local community and that recruitment efforts are culturally appropriate and effectively reach the target population(s). Performance monitoring includes tracking baseline information, effort, requests and considerations, and results. Performance monitoring uses only aggregate data and personal information is not released.
Community Workforce Agreements (CWAs) and Project Labor Agreements (PLAs) can be effective means for achieving equity and opportunity employment goals.

This sub-measure considers whether an agreement will be in place to have a have a minimum percent of construction apprentice hours performed by traditionally disadvantaged and underutilized populations as defined by appropriate community-based and public organizations (e.g., targeting low income populations, women, persons of color, veterans, disabled individuals, or formerly incarcerated individuals). A project earns bonus points depending upon the level of commitment to equity and opportunity apprentice hiring. The points are awarded as a bonus so that projects are not penalized if the pool of available apprentices does not include the target population. Projects earn 100 bonus points for a binding agreement to have a minimum of 30% of apprentice construction employment hours performed by traditionally disadvantaged and underutilized populations as defined by appropriate community-based and public organizations; 75 points if the binding agreement is for a minimum of 20% of apprentice construction employment hours; 50 points if the agreement is non-binding; and 0 points if no agreements will be made. The sub-measure is not applied if the investment does not include any construction activity.

Caveats
Evidence to support the claim should be made available. Consideration should be given to the representativeness of the stakeholders involved, the quality of the agreement, and the strength of implementation provisions.

d) Equity and Opportunity Non-Apprentice Hiring Goals
Hiring goals that are well defined and executed can facilitate access to construction trade employment by traditionally disadvantaged and underutilized populations. Hiring goals should be defined with relevant community and agency input in order to ensure that they respond to the unique context of the community and project. Outreach and recruitment efforts should be tailored to effectively reach the target population(s), and progress toward access and advancement goals monitored over time. Collaboration is important for ensuring that goals reflect the needs of the local community and that outreach and recruitment efforts are culturally appropriate and effectively reach the target population(s). Performance monitoring includes tracking baseline information, effort, requests and considerations, and results. Performance monitoring uses only aggregate data and personal information is not released. Community Workforce Agreements (CWAs) and Project Labor Agreements (PLAs) can be effective means for achieving equity and opportunity employment goals.

This sub-measure considers whether agreements are in place to have a minimum percent of non-apprentice construction employment hours performed by traditionally disadvantaged and underutilized populations as defined by appropriate community-based and public organizations (e.g., targeting low income populations, women, people of color, veterans, disabled individuals or formerly incarcerated individuals). A project earns 100, 75, 50, or 0 points depending upon the level of commitment: 100 points for a binding agreement to have a minimum of 30% of non-apprentice construction employment hours performed by traditionally disadvantaged and underutilized populations as defined by appropriate community-based and public organizations; 75 points if the binding agreement is for a minimum of 20% of non-apprentice construction employment hours; 50 points if the agreement is non-binding; and 0 points if no agreement will be made. The sub-measure does not apply if the investment does not include any construction activity.
Caveats
Evidence to support the claim should be made available. Consideration should be given to the representativeness of the stakeholders involved, the quality of the agreement, and the strength of implementation provisions.

e) Equity and Opportunity in Business Development
Inclusive strategies that support participation of underrepresented businesses in project construction contracts include culturally competent outreach, as well as targeted assistance with barriers to participation (e.g., forms, bonding, insurance). Efforts should be tailored to effectively reach the target population(s), and progress toward access and advancement goals monitored over time. Collaboration is important for ensuring that goals reflect the needs of the local community and that efforts are culturally appropriate and effectively reach the target population(s). Performance monitoring includes tracking baseline information, effort, requests and considerations, and results. Performance monitoring uses only aggregate data and personal information is not released. Community Workforce Agreements (CWAs) and Project Labor Agreements (PLAs) can be effective means for achieving equity and opportunity goals.

This sub-measure considers whether an agreement will be in place to utilize, mentor, partner or otherwise support participation of under-represented businesses in project construction contracts. A project earns 100 points if a binding agreement will be in place, 50 points if a non-binding agreement will be in place, and 0 points if no agreement will be in place. The sub-measure is not applied if the investment does not include any construction activity.

Caveats
Evidence to support the claim should be made available. Consideration should be given to the representativeness of the stakeholders involved, the quality of the agreement, and the strength of implementation provisions.

Performance Area: Sound Investment

Why Does This Matter?
A sound investment is defined here as one that is fiscally responsible and supports economic vitality. Determining the financial viability of an investment at the project level and community level is essential in order to protect investors and taxpayers. Conservative estimates and sensitivity analysis (e.g., considering outcomes under various assumptions such as low, medium, and high) can help produce realistic estimates of financial viability. In addition, economic vitality and efficient deployment of capital may be facilitated when investments align with regional economic development goals and strategies, leverage additional resources, and retain dollars in the local economy.

What Do We Want To Know?
• Does the project appear to be financially viable for investors and taxpayers?
• Does the project align with regional economic development goals and strategies?
• Do other investors support the project?
• Is the project likely to retain dollars in the local economy?
What Measures Were Selected to Operationalize This Performance Area?

The Sound Investment performance area measures are:

• Pro Forma Completed
• Fiscal impact Analysis
• Consistency with Regional Economic Development Strategy
• Support for Local Business
• Ratio Private to Public Investment
• Leveraged Investment

The sound investment performance area is calculated by averaging the scores for four measures: pro forma completed, fiscal impact analysis conducted, consistency with regional economic development strategy, and support for local business. Information regarding the amount of leveraged investment and the ratio of public to private investment is displayed, though is not calculated as part of the project score.

1. Pro Forma Completed

A pro forma provides financial projections for a project’s expected revenues and expenses. Assumptions used in creating the projections should be disclosed and conservative estimates used. This important due diligence procedure is designed to assess profitability of the investment, a key component of triple bottom line performance.

Measure Formula and Scoring
This measure considers whether a pro forma has been completed that demonstrates the financial viability of the proposed project. A project earns 100 points if a pro forma has been completed by a qualified professional analyst and demonstrates financial viability of the proposed investment. No points are earned if a pro forma by a qualified professional analyst has not been conducted which demonstrates financial viability of the proposed investment.

Caveats
Evidence to support the claim should be made available and consideration given to the quality of the analysis.

2. Fiscal Impact Analysis

Fiscal impact analysis considers budgetary impacts associated with an investment. For example, will the investment lead to increased costs of services and, if so, is there a corollary revenue stream to cover those costs? Effective fiscal impact analyses account for full costs and revenues and clearly identify assumptions regarding impacts, timeframes, and expenses.

Measure Formula and Scoring
This measure applies if the project will be a recipient of public investment. A project earns 100 points if a fiscal impact analysis has been completed and demonstrates neutral or net positive impact. No points are earned if a fiscal impact analysis has not been conducted or if a neutral or net positive impact has not been identified. If the project is not a recipient of public investment, this sub-measure does not apply.
**Caveats**
Evidence to support the claim should be made available and consideration given to the quality of the analysis. The quality of fiscal impact analysis can vary and attention should be given to the data used as well as assumptions regarding trends, time periods, and geographic boundaries. The analysis should use conservative numbers and account for uncertainty by considering a range of scenarios (e.g., low, medium, high projections).

This measure only applies to projects that receive public investment, although fiscal impacts of projects that do not receive public investment may be significant. Consideration should be given as to whether this measure should apply to other investments as well and, if so, what those may be.

**Alternatives Considered**
The option of integrating fiscal impact review into the TBL Tool was considered but determined not to be feasible at this time (e.g., data requirements to accommodate all jurisdictions and project types in the U.S.). A number of fiscal impact tools are available at varying levels of precision and cost. The Federal Reserve Fiscal Impact Tool (FedFit) may be particularly useful for small or resource-constrained communities (http://www.federalreserve.gov/forms/fiscalimpactrequest.aspx; http://www.knowledgeplex.org/download-doc.html?id=188306).

**Additional Information**

**3. Consistency with Regional Economic Development Strategy**

Although globally connected, economies cohere at a regional scale where businesses access talent, amenities, and infrastructure that span local political boundaries. Quality regional economic development strategies identify regional assets and prioritize investments that position the region for economic strength and resilience — the ability to generate and retain wealth in the community and successfully weather disruptions or changes to the economy. Aligning investment with high quality
regional economic development strategies helps to ensure that scarce resources are used effectively and strategically.

Measure Formula and Scoring
This measure assigns 100 points if the investment aligns with and supports the region’s economic development strategy. This may be a CEDS (Comprehensive Economic Development Strategy) or appropriate regional comprehensive plan with economic development element. No points are earned if the project does not align with the region’s economic development strategy or if alignment has not been verified. If the project is located in an area that does not have a regional economic development strategy this measure is scored as “NA” and the score for the proposed investment is not affected.

Caveats
Evidence to support the claim should be made available including the portion of the economic development strategy that is supported by the proposed investment.

The quality and currency of economic development strategies varies. It is possible that a proposed investment could be an excellent fit for the community and region even though this is not reflected in the relevant economic development strategy. Beta testing should observe for this condition and potential accommodations should be explored.

Alternatives Considered
A number of factors influence the economy, and there are no “magic formulas” with respect to creation and maintenance of economic strength and resilience. At the same time, there are strategies that in general work together to produce a more robust and resilient economy. These include creating and maintaining basic (export) industries that bring dollars into the economy, fostering sector and firm diversity to enhance cluster strengths and reduce vulnerability associated with dependence on specific companies or industries, building on assets and strengths, and plugging leakages in the local economy (keeping dollars local via import substitution). A lot of attention is currently given to the concept of clusters – geographic concentrations of interconnected companies, specialized suppliers, service providers, and associated institutions. Current research suggests that clusters can be important for producing employment growth, innovation, and high wages. The cluster concept is related to traditional measures of basic and non-basic industries (export and local servicing), however, it considers linkages and interconnections between industries that comprise a cluster rather than simply a sector on its own (i.e., location quotient (LQ) for grouping of sectors versus LQ for a sector).

The option of reviewing a proposed investment’s fit with existing or emerging clusters and impact on regional economic diversity (e.g., number of types of industries or distribution of employment across industries) was considered, however, project advisors recommended against using these measures due to concerns regarding appropriate scoring frameworks (e.g., determining what is a good or bad level of diversification), concerns with data, and because the measure considering fit with regional economic development strategy was viewed as sufficiently capturing the intent behind these alternatives (i.e., will the project support economic vitality rather than does the project support diversification or cluster development). Should interest in a measure considering investment support with an existing or emerging cluster remain strong, advisors have recommended an option for the user to identify an appropriate cluster study for the area.
Additional Information

4. Support for Local Business

Purchasing goods and services from locally owned and operated businesses can be an effective way to inject dollars into the local economy and thereby help to keep businesses open, people employed, and streetscapes vibrant. It can, however, ignore regional comparative advantages, increase the cost of inputs, lower overall efficiency and reduce aggregate growth at the national or global scale. Determining when to patronize locally owned and operated businesses will depend upon the context. For example, if the local option for a given good or service has significantly higher costs or lower quality, then impacts to competitiveness or satisfaction suggest that the non-local option may be preferable. This measure aims to support local economic vitality by encouraging consideration of local impacts of purchase decisions.

Measure Formula and Scoring
This measure assigns 100 bonus points if there is a program or policy in place to prioritize or encourage the purchase of goods and services from businesses that are owned and operated in the metropolitan area, micropolitan area, or county in which the project is located (i.e., supports retention of dollars in the local economy when appropriate. No bonus points are earned if there is not a program or policy.

Caveats
Evidence to support the claim should be made available.
5. Ratio of Private to Public Investment

In many instances, public-private financing partnership is essential to project viability. This is particularly the case when a project serves important public objectives but has low financial returns (e.g., infrastructure, affordable housing), or when there is a higher than average degree of risk or cost (e.g., regeneration area). At the same time, fiscal responsibility and stewardship of public dollars suggests that due diligence be given to ensure that the level of private investment is appropriate to the context.

Measure Formula and Scoring

No points are provided for this measure and the information is not included in the overall project score. While this information may be useful to an investor, it is not empirically tied to the bottom line: there is no definition of a “good” or “bad” mix of public/private investment. Thus, this information is not included in the score. The information provided includes the amount of private investment, the amount of public investment, and the ratio of the two (i.e., private dollars/public dollars).

Caveats
Evidence to support claims should be made available.

6. Leveraged Investment

The presence of additional project funding is often requested by potential investors in order to assess project support and/or minimize risk.

Measure Formula and Scoring

No points are provided for this measure and the information is not included in the overall project score. While this information may be useful to an investor, it is not empirically tied to the bottom line: there is no definition of “good” or “bad” amounts of leverage. Thus, this information is provided but is not included in the score. The information provided includes the funding request, the total project cost, and the ratio between the two (i.e., 1: (Total project cost – Funding request)/Total request).

Total project costs include hard and soft project costs of development including land, infrastructure directly contributing to the project, and land remediation or preparation. Land value is the purchase price or, if donated, the assessed value of land donated with zero as the minimum (i.e., no negative value if the site is a brownfield). Tax incentives that accrue as potential reductions in future government revenues rather than direct capital outlays are not included in total direct project costs. This important TBL element is addressed in the TBL Tool in the accountability and fiscal impact measures. Also, the TBL Tool can be used to assess the TBL of a proposed tax incentive investment, in which case the estimated contribution would appear as the funding request.

Caveats
Evidence to support claims should be made available.
Goal: Natural Resource Stewardship

Natural resources provide essential inputs to economic activity, contribute to quality of life and place-based economic development, and sustain life. Business leaders are increasingly recognizing that natural resources must be appropriately valued and maintained if business profitability and viability are to endure.6

In the TBL Tool, the natural resource stewardship goal is comprised of three performance areas: industry eco-efficiency, green design and construction, and green operations. An investment’s natural resource stewardship score is calculated by averaging its scores for these three performance areas, as described below.

The following information details why each performance area is important, the measures selected to operationalize the performance area, the measure formulas and scoring, and any data limits or caveats.

Performance Area: Industry Eco-Efficiency

Why Does This Matter?
Efficient use of scarce resources (factors of production) can contribute positively to the bottom line, while maintaining resource availability and quality for the future. This performance area considers the efficiency with which the project industry or industries employ natural resources to create or retain jobs. For example, if one investment creates 100 jobs and produces 10 tons of pollution in the process and another investment creates 100 jobs while emitting fewer tons of the same pollutants, all other things being equal, the second investment is a more eco-efficient generator of jobs.

What Do We Want To Know?
• Are natural resources being used efficiently to create and retain jobs?

What Measures Were Selected to Operationalize This Performance Area?
Resource use and environmental emissions per job created at the sector level are considered. Three measures consider the amount of resource use per job (i.e., water, land, fossil fuel use) and six consider the amount of environmental pollution created per job (i.e., air pollution, ozone depletion, greenhouse gases, ecotoxicity, eutrophication).

Measure Formula and Scoring7
This performance area score is calculated by averaging the project’s scores on nine eco-efficiency measures: three that consider the amount of resource use per job (i.e., water, land, fossil fuel use) and six that consider the amount of environmental pollution created per job (i.e., air pollution, ozone depletion, greenhouse gases, ecotoxicity, eutrophication).

6 For example, the case was made for such an approach in The New Business Imperative: Valuing Natural Capital – a report produced by an invitation-only membership organization of senior level executives representing corporations such as Dow Chemical, Disneyland, Marriott, Kimberly-Clark, General Motors, and Unilever. http://www.corporateecoforum.com/valuingnaturalcapital/.
7 Portions of this text were contributed by Dr. Sangwon Suh, University of California at Santa Barbara and Industrial Ecology Research Service, LLC.
The environmental impact per job created and retained is determined based on the industry or industries in which the jobs are located. The environmental impact associated with a sector is calculated taking a “cradle to gate” lifecycle approach which includes all of the impacts from upstream supply-chain processes that are inputs to the sector through to the point of sales to end-consumers (i.e., household consumers, business consumers, government consumers and exports). The impact calculations are based on environmental life cycle assessment (LCA) – a technique that accounts for the environmental impacts associated with a product (goods and services). Environmental impacts (stressors) include the natural resources consumed and pollutants emitted across the life of the product – from acquisition of raw materials, to manufacturing, use, and waste management (disposal, reuse, or recycling). “Cradle to grave” analyses consider impacts through product end of life (waste management), while “cradle to gate” analyses consider impacts through factory gate (manufacturing). Social life cycle assessment and life cycle costing are important emerging fields within LCA, however, our attention here is restricted to environmental impacts.

Scoring is determined by whether a project’s industry produces jobs with relatively more or less efficient use of resources. Because no standards exist for “environmental impact per job created” (e.g., no amount of water per job that is designated as good or bad), the scoring is based on best and worst performers overall (e.g., relatively better or worse than other industries on a normalized 0 to 100 scale). Industries or sectors are defined using the North American Industry Classification System (NAICS) (http://www.census.gov/eos/www/naics/) – the standard for categorizing businesses by sector or industry. The NAICS level requested in the TBL Tool depends upon the amount of variation within an industry; more detailed information is requested only where differences among the types of companies within a given NAICS level are significant. For most industries, the user is asked to identify the three-digit level NAICS (retail and wholesale stop at the two-digit level, while a few others go one or two levels deeper). The TBL Tool user identifies the industry codes (NAICS) using a pull-down menu on the website. When a project includes multiple industries or NAICS, a weighted average is used. For example, if the project includes three NAICS that scored 50, 60, and 80, and the project’s relative portion of jobs for each of those NAICS is 20%, 30%, and 50%, then the score would be computed as (.20*50) + (.30*60) + (.50*80) = 68.

There are two main approaches to environmental LCA: “bottom up” LCA is based on site-specific information gathered across the life-cycle of a product, and “top-down” LCA is based on input-output tables that describe flows of goods and services between industries (sectors). The bottom-up (process-based) approach allows for precision and detail, but requires significant resources and can suffer from “truncation errors” associated with decisions regarding how far up the supply-chain to set boundaries for data inclusion. The top-down approach incorporates information about environmental stressors into industry input-output (I-O) tables, thus enabling analysis of environmental impacts at the sector level. Process-based LCA can misrepresent impacts by excluding important upstream processes, while I-O LCA can misrepresent impacts due to the coarseness of the data (i.e., if averages mask significant variation in a sector). However, while I-O LCA may not be suited to detailed comparisons at the product design level, it is generally suited to macro level policy decisions such as consideration of overall impacts of a system or comparing different options. By providing an indication of the relative environmental impact of various industries, IO-LCA provides valuable information to investors seeking to produce jobs with the least environmental impact.

The scores for this performance area are based on the Comprehensive Environmental Database Archive (CEDA) – an internationally recognized model that specifies environmental impact per dollar of final demand for each input-output (IO) sector. The Comprehensive Environmental Data Archive (CEDA) is an
I-O LCA database that quantifies natural resource use and environmental emissions associated with a product’s life cycle. CEDA has been used by federal agencies such as the U.S. Department of Commerce and U.S. Environmental Protection Agency (EPA) and was determined to be an appropriate input-output life cycle analysis database for this application given its prior use by federal agencies and reputation for robustness and accuracy.

The Beta version of the TBL Tool was built with the CEDA 4 database, which uses the most detailed U.S. input-output table compiled by the Bureau of Economic Analysis (BEA) of the U.S. Department of Commerce (DOC) along with various environmental statistics and models. The results represent the national average cradle-to-gate environmental impact of each product distinguished in the input-output table. Cradle-to-gate is used synonymously with total (direct and indirect) environmental impact and includes impacts from all upstream supply-chain processes to the point of sales to end-consumers, i.e., household consumers, government consumers and exports. References to detailed information about CEDA data and methods can be found at the end of this section.

CEDA 4 evaluates each I-O sector on thirteen different environmental impact categories following mostly the Tool for the Reduction and Assessment of Chemical and Other Environmental Impacts (TRACI) Method developed and used by the U.S. EPA. The impact categories reflect best available science and societal consensus. Impact categories in Life Cycle Impact Assessment (LCIA) are developed through a step called “characterization,” which uses scientific findings to quantify the environmental impacts of various stressors to each environmental impact category, and to aggregate these into an equivalency of a single stressor, called a category indicator, for each impact category. The CEDA 4 impact categories and category indicators used for this performance area are presented below, along with a description of the potential environmental harm. References regarding the TRACI method can be found at the end of this section.

The input-output tables produced by the U.S. Department of Commerce Bureau of Economic Analysis (BEA) account for the flow of goods and services from industry to industry and to final users. The BEA I-O tables use an industry and product classification system derived from the North American Industry Classification System (NAICS). CEDA specifies environmental impact per dollar value of output8 for each input-output (I-O) sector (see Suh 2005 for details on how this is calculated). This includes both direct and lifecycle environmental impact information by IO sector. Direct impacts are those produced by the sector itself whereas lifecycle impacts include impacts from across the product life cycle. As noted above, CEDA 4 uses the TRACI method to define environmental impact per dollar value of output.

Environmental impact per dollar of output by I-O sector was converted to environmental impact per lifecycle job for each sector in order to meet the needs of the TBL Tool. Environmental impact per lifecycle job was computed by dividing total impact per I-O sector by the sector’s total lifecycle employment. Lifecycle jobs includes all of the direct jobs associated with upstream supply-chain processes that are inputs to the sector through to the point of sale to end-consumers (i.e., household consumers, business consumers, government consumers, and exports). Data for lifecycle employment per I-O sector was derived from the November 2004 Bureau of Labor Statistics (BLS) Occupational Employment Statistics (OES), listed by 5-digit, 4-digit, 3-digit, and 2-digit North American Industry Classification System (NAICS) codes (http://www.bls.gov/oes/oes_dl.htm). Because the BLS employment statistics for agricultural sectors was highly aggregated, data from the 2002 U.S.

---

8 Dollar value of output is defined as producers price = consumers price minus transportation margin and wholesale and retail margin.
Department of Agriculture (USDA) Census was used for sectors that had available USDA data (http://www.agcensus.usda.gov/Publications/2002/USVolume104.pdf). BLS and USDA do not provide employment data for every IO sector. In these instances, direct employment was estimated by dividing the total compensation for that industry (which is available for every IO sector) by the average annual wage of a more aggregated industry category (available from BLS). For example, if there was no employment data for industry category 212210 (Iron Ore Mining), but there was for 212200 (Metal Ore Mining), then employment was estimated as the total worker compensation for Iron Ore Mining divided by the average annual wage for Metal Ore Mining. If Metal Ore Mining had no employment data either, the average annual wage for industry category 212200 (Mining, Except Oil and Gas) would be used, and so forth. Several of the I-O sector codes are a combination of more than one NAICS code. If employment data was available for each component NAICS code, then that employment data was summed to give the total direct employment for the IO sector. If employment data was missing for any of the component NAICS codes, then employment was estimated using the method described above.

The eco-efficiency measures helps identify whether the proposed project belongs to an industry that has greater or lesser environmental impact per lifecycle job relative to other industries. This information can be useful for identifying potential issues and engaging with developers to design the project for best possible outcomes. At the same time, a project may belong to an industry that is low performing relative to other industries but is expected to have strong environmental performance relative to other projects in the same industry (e.g., the project belongs to a high water use industry but will have innovative water reduction and recycling features). Projects with strong performance relative to their industry will be able to earn points for their leadership in the green operations performance area. The nine measures for the eco-efficiency performance area are displayed in the table below, along with their units of measurement and potential impacts.

* Three human health measures (impact categories) are listed in the Environmental Health Performance Area of the Community Well-Being Goal.

** Impact categories that are not included in the original TRACI method but that are included in CEDA.

*Caveats*

Estimated impacts are limited to the data collected. Thus, while the data provide a good indication of relative environmental impact of various sectors, there is no consideration of impacts for which data is not collected (despite their potential significance). Also pertaining to significance of impact, while the results provide a sense of how sectors perform relative to each other, they do not provide a sense of performance with respect to a health or safety threshold (e.g., no thresholds are set for kilograms per lifecycle job created so the data cannot be used for scoring based on a threshold beyond which a project is clearly problematic). Neither do they consider background conditions or simultaneous impacts and interactions. IO-LCA provides valuable information regarding environmental impacts but is not a substitute for risk assessment.

Because the environmental data and USDA employment data was from 2002 and the BLS employment data was from 2004, sectors whose environmental impacts or employment have changed dramatically in the last decade may not be as accurately represented by the data. For the industries that have gone through rapid changes in terms of their production process, material intensity of production, environmental emission profiles and water and land use patterns since 2002, the result may not accurately reflect the current conditions. The Bureau of Economic Analysis produces Benchmark survey input-output tables once every five years ([http://www.bea.gov/](http://www.bea.gov/)). The tables for the 2002 base year were the most recent data available at the time the TBL Tool was constructed. If an industry’s position relative to others has changed significantly, the significantly this could impact scoring. Future versions of the TBL Tool should consider whether an investment should be made in updating the CEDA scores when more current information is available.

The environmental impacts are modeled based on U.S. average condition and, thus, provide a coarse estimate of industry impacts. Projects may be misrepresented by the CEDA results if their activities deviate substantially from industry averages, regional conditions are much different from the national average, or industry environmental impact or employment have changed dramatically relative to other industries since the CEDA 4 data was compiled. Consequently, the data produced for these measures should be viewed as rough estimates that provide guidance on the likely impact of a project relative to projects in other sectors. Where appropriate, more detailed project specific environmental assessments should be conducted.

*Alternatives Considered*

Environmental Input Output Lifecycle Analysis is an efficient method for estimating the direct and total environmental impacts associated with economic development without conducting detailed project specific environmental studies. CEDA is not the only database capable of supporting this approach, but it was deemed to be the most complete and accessible for this project.

Performance Area: Green Design and Construction

Why Does This Matter?
Buildings and infrastructure that are designed and maintained for efficiency and environmental quality can provide cost savings (e.g., lower energy and water consumption), add value (e.g., higher worker productivity and satisfaction, higher rents, or faster sales), and contribute to conservation of ecosystems.

What Do We Want To Know?
• Does the project utilize best practices for green building/infrastructure construction, including adaptive reuse where appropriate?
• Does the site design follow best practices for low impact/sustainable site design?
• Does the project remediate or restore lands?
• Are sensitive natural resource areas avoided?

What Measures Were Selected to Operationalize This Performance Area?
The Green Design and Construction performance area measures are:
• Green building and construction
• Adaptive reuse
• Sustainable site design
• Remediation or restoration of lands
• Avoidance of sensitive natural resource areas.

The performance area score is calculated by averaging the project’s scores for the five measures.

1. Green Building and Construction

Green building and construction practices can positively impact the triple bottom line through energy cost savings, increased building value, higher occupant satisfaction and productivity, and/or lower impacts to human and natural resource health.

Measure Formula and Scoring
This measure considers whether green building practices will be applied in new construction as well as in remodels or upgrades. A project earns 100, 75, 50, or 0 points depending upon the level of commitment to green building and construction. Maximum points are provided if the project will receive third party certification by a recognized international, national, or regional program for green construction (e.g., LEED, Living Building Challenge, Green Globes, EarthCraft, Earth Advantage, GreenLITES, or an official government program). Third party certification is valuable because it provides a common standard for accepting and verifying claims buildings and infrastructure can be green without certification. Seventy-five points are earned if the applicant can demonstrate that plans are in place to build to third party standards although without certification. Fifty points are provided if the project will employ some green building features such as water or energy conservation, but will not design and build to a recognized third party standard. No points are earned if there are not documented commitments to green building.

Some certification programs address green operation and maintenance along with green building or green site design. If the project will be certified by a program that addresses both or all three (green
construction, sustainable site design, green operations and maintenance), the applicant simply answers appropriate to specific measure (i.e., not expected to secure three different certifications).

**Caveats**
Evidence to support claims should be made available.

Buildings and infrastructure can be green without certification or, conversely, can have certification without outstanding performance. While acknowledging these challenges, certification provides a common standard for accepting and verifying claims that is more helpful than having no standard at all. The scoring framework provides a mechanism to provide points for projects that employ green practices without certification but assigns the highest score when third party certification is present.

2. **Adaptive Reuse**

Reuse of existing facilities can provide a number of environmental benefits depending upon the type of project and materials used. Environmental benefits associated with rebuilding rather than razing facilities include savings in energy, material, land conversion, and carbon emissions.

**Measure Formula and Scoring**
This measure does not affect the project score when facility reuse is not an applicable or appropriate option. Where it does apply, this measure assigns a bonus score of 100 points to projects that make use of an existing structure.

**Caveats**
Evidence to support claims should be made available.

3. **Sustainable Site Design**

Site design exerts a powerful influence over economic, environmental, and social impacts of a project. These include, for example, groundwater recharge, flood control, habitat conservation, increased recreation opportunities, and reduced maintenance costs. Sustainable site design works with nature to ensure that beauty and accessibility are maximized, while long term costs associated with site development are minimized.

**Measure Formula and Scoring**
This measure considers whether the project aligns with recognized sustainable site design standards, certifications, or best practices. A project earns 100, 75, 50, or 0 points depending upon the level of commitment to sustainable site design. Maximum points are earned if the project will receive third party certification by a recognized international, national, or regional program (e.g., Sustainable Sites, LEED-ND, One Planet Communities). Third party certification is valuable because it provides a common standard for accepting and verifying claims. Seventy-five points are earned if the applicant can demonstrate that plans are in place to build to best practices or third party standards although without certification. Fifty points are provided if the project will incorporate low impact or sustainable site design features but will not be designed and built to the standards of a recognized international, national, or regional program.
If the project will receive certification by a program that addresses both site design and construction, simply answer the questions appropriate to the respective measure (i.e., a project is not expected to secure separate or redundant certifications).

Some certification programs address green operation and maintenance along with green building or green site design. If the project will be certified by a program that addresses both or all three (green construction, sustainable site design, green operations and maintenance), the applicant simply answers appropriate to specific measure (i.e., not expected to secure three different certifications).

Caveats
Evidence to support claims should be made available.

Site design can be green or sustainable without certification or, conversely, can have certification without outstanding performance. While acknowledging these challenges, certification provides a common standard for accepting and verifying claims that is more helpful than having no standard at all. The scoring framework provides a mechanism to provide points for projects that employ sustainable site design without certification but assigns the highest score when third party certification is present.

4. Remediated or Restored Lands

The U.S. EPA estimates that there are more than 450,000 brownfields (abandoned, idled, or under-utilized industrial or commercial facilities) in American communities. Remediation of abandoned or contaminated sites can increase property values and tax revenues while reducing health costs. Restoration of natural resources (e.g., wetlands, forestlands, rivers, or farmlands) can deliver valuable ecosystem services such as flood control, wildlife habitat, and scenic amenities. Restoration or remediation of natural resources can take many forms, including farmland for food production, reforestation and afforestation, stream restoration, or de-paving.

Measure Formula and Scoring
Bonus points are earned if the project contributes to land or habitat remediation or restoration. The site may or may not be classified as a brownfield, and restoration and remediation activities are defined broadly including farmland for food production, reforestation and afforestation, and de-paving. Projects that do not include remediation or restoration are not penalized, as this is a bonus measure.

Caveats
Evidence to support claims should be made available.

Alternatives Considered
Scoring does not consider the order of magnitude of the remediation or restoration. There is no appropriate standard for a “good” or “bad” amount of restoration in total acres (e.g., 10), relative site portions (e.g., 10%), or acres per job created (e.g., .10 acres per job). A site may be small and/or may have no need or opportunity for remediation or restoration. Thus, this measure simply considers whether remediation or restoration occurs and, if so, provides a bonus point for the contribution.
5. Avoidance of Sensitive Natural Resources

Natural resources provide a variety of functions that have significant economic value. Referred to as ecosystem services, these functions include provisioning (resources are provided), regulation (resources provide safety or balance such as flood control or oxygen levels), and cultural (resources provide aesthetic, historic, and other cultural benefits). Protection of sensitive natural resources is important for ensuring that ecosystem services remain functional, that mitigation and repair costs associated with disrupted environmental systems are minimized, and that resource-based economies remain viable.

Measure Formula and Scoring
This measure considers eight sensitive natural resource areas: flood zones, critical habitat, steep slopes, wetlands, water bodies, protected areas, prime farmland, and forestland. Based on the project location provided, the TBL Tool calculates whether the proposed project is in any of the eight sensitive natural resources or the necessary buffer as appropriate. Each sensitive resource is scored separately. For five of the sensitive resources (flood zone, critical habitat, steep slope, protected area, or wetland), a project located in the resource or its buffer zone earns no points because avoidance is the preferred option. For three of the sensitive natural resources, (prime farmland, forestland, and water body), a project located in the sensitive resource or its buffer zone receives a mid-score (50) in recognition that development in these areas may be more easily accommodated and/or mitigated than with other sensitive resources. Maximum points (100) are earned if a project is not in a sensitive natural resource area or its buffer zone. The score for the sensitive natural resource measure is calculated by taking the lowest of the eight sensitive resource sub-scores (i.e., 0, 50, or 100).

Scoring favors investments that are not located in sensitive natural resource areas or their buffers. Projects that are located in these areas and provide a mitigation or enhancement function can capture points for those efforts in the restoration and remediation measure (e.g., a project that includes stream restoration).

The sensitive natural resource area data and definitions are detailed below. Buffers were added where appropriate in order to provide a margin for inaccuracies in the mapping (e.g., precision of data or user defined boundaries) and to help protect sensitive lands from "edge effects" where noise, pollution or other pressures penetrate from the development into the core of the protected area. Data sets and buffers are defined as follows:

- **Flood Zone** – Flood zones are geographic areas that the Federal Emergency Management Agency (FEMA) has defined according to varying levels of flood risk (http://www.msc.fema.gov/webapp/wcs/stores/servlet/info?storeId=10001&catalogId=10001&langId=-1&content=floodZones&title=FEMA%20Flood%20Zone%20Designations). High Risk areas (Zones A, V) are defined for the TBL Tool (100 year flood zones). The TBL Tool uses digitized FEMA designated flood zones. However, these maps do not currently have full coverage. If the project is identified as being in or near a FEMA designated flood zone, the score is 0. If it is not, the score is NA, though this should be confirmed.

- **Critical Habitat** – The TBL Tool identifies critical habitat areas determined by the U.S. Fish and Wildlife Service to be essential to the conservation of threatened or endangered species under the U.S. Endangered Species Act. In the future, the TBL Tool may be able to use Eco-IPaC, a system being developed by U.S. Fish and Wildlife Service, in partnership with Department of Homeland Security, U.S. Geological Survey (USGS), and Department of Transportation (DOT). The Information, Planning, and
Conservation (IPaC) System identifies areas where there are threatened or endangered species of concern and includes appropriate buffers. Eco-IPaCare notes all affected species (not all species have designated critical habitat, so their tool is superior). Eco-IPac was not available at the time the TBL Tool was under construction.

- Steep Slopes – The U.S. Soil Survey Geographic (SSURGO) Database, built by U.S. Department of Agriculture (USDA) Natural Resource Conservation Service (NRCS) from the National Cooperative Soil Survey, is used to identify whether the proposed project is in a map unit (i.e., an area or polygon) in which some or all of the land is sloped 25% or greater. The steep slope buffer is set at 65 feet. Much of the scientific literature that discusses mitigation techniques for landslide hazard areas recommends setbacks or buffers from the toe and top of the hazard area. However, there is no empirical evidence to support recommendations for specific or standardized setback requirements. Nevertheless, many local ordinances recommend a 50’ buffer plus an additional 15’ building setback, subject to specialized geotechnical study, in order to minimize the risk of damage resulting from land sliding and erosion of the steep slope caused by adjacent development. Regulation of development on steep slopes may address such concerns as human safety, natural resource protection, or scenic quality. Slopes between 15% and 25% are often regulated but without prohibition (i.e., caution must be exercised but its they are buildable).

Additional Information
City of Lake Forest Park, WA. June 2011. “Steep Slope Hazard Areas.”

King County, WA. n.d. “Critical Areas Ordinance Users Manual.”

- Wetlands – The National Wetlands Inventory published by the U.S. Fish and Wildlife Service is used to identify wetlands including transitional areas between terrestrial and aquatic systems where the water table is usually at or near the surface or the land is covered by shallow water. The wetlands dataset does not cover Wisconsin and projects receive a NA score for this sub-measure. We recommend that the project location relative to wetlands be confirmed. The wetlands buffer is set at 300 feet. Scientific studies show that a 300’ buffer is commonly sufficient to protect water quality and wildlife functions, though many ordinances require less and some scientific studies suggest more (up to 5000’ feet, depending on the species). Several
ordinances set 500’ as a distance for greater regulatory review but may only require non-disturbance nearer the wetland and restricted development up to 500’ or more.

Additional Information

ohioline.osu.edu/aex-fact/pdf/AEX44502FloodplainsandStreamwaySetbacks.pdf.

• Water Bodies – The U.S. Geological Survey (USGS) National Hydrologic Database is used to identify standing and flowing water bodies including stream/river, lake/pond, swamp/marsh, reservoir, playa, estuary, and ice mass. The water bodies buffer is set at 300 feet. Scientific studies show that a 300’ buffer is commonly sufficient to protect water quality and wildlife functions, though many ordinances require less and some scientific studies suggest more (up to 5000’ feet, depending on the species). Several ordinances set 500’ as a distance for greater regulatory review but may only require non-disturbance nearer the water body and restricted development up to 500’ or more.

Additional Information

ohioline.osu.edu/aex-fact/pdf/AEX44502FloodplainsandStreamwaySetbacks.pdf.

• Protected Areas – The U.S. Geological Survey (USGS) Gap Analysis Program (GAP) Protected Areas Database (PAD-US) includes national parks and forests, public lands generally, wildlife preserves, state and local parks and reserves, lands held by non-profit organizations and many other areas. In the PAD-US, protected areas are lands held in fee ownership for permanent or very long term open space uses and include public land ownership, management and
conservation lands nationally, and voluntarily provided privately protected areas. The protected area buffer is 150 feet. Conservation biologists recommend that core protected areas be surrounded with buffer zones in which human activities that are compatible with conservation may be allowed (e.g. education and recreation). Beyond that an additional transition zone is recommended with farms and settlements designed to be compatible with the healthy functioning of the conservation area. The width required depends on the impacts being mitigated. These can include reducing poaching/collecting, noise and visual impacts, natural disturbances, and invasive/predatory species. Unfortunately, clear standards for these buffers have not emerged. One example in practice comes from Pima County where a 1 mile buffer around the Saguaro National Park and other protected areas was established to ensure that land developments protects habitat outside the protected areas that may be important to protected area residents and is designed to be visually compatible with recreational uses inside the protected zone. Since the size of the appropriate buffer width varies according to circumstances it may be useful to include ¼ and 1 mile buffers as an alert item.

Additional Information

• Prime Farmland – The USDA Natural Resource Conservation Service Soil Survey Geographic (SSURGO) Database is used to identify prime farmland – areas that have the best combination of physical and chemical characteristics for producing food, feed, forage, fiber, and oilseed crops and that are available for these uses.

The prime farmland buffer is 150 feet. Buffers are intended to separate farmland from urban uses in order to reduce the conflicts between the uses, protect urban property values, and sustain agriculture. Conflicts can arise from dust, noise, chemical use, odors and other factors associated with farm operations.

Additional Information

• Forestland – The USGS National Land Cover Database is used to identify forestland. The National Land Cover Database (NLCD) serves as the definitive Landsat-based, 30-meter resolution, land cover database for the Nation. The next version of NLCD, entitled NLCD 2011, is currently in production and is scheduled for public release in December 2013 (http://pubs.usgs.gov/fs/2012/3020/). The 2006 forestland data set does not cover Alaska or Hawaii and projects receive a NA score for this sub-measure. We recommend that project location relative to forestlands be confirmed. The forestland buffer is 150 feet, as are the buffers for agriculture and protected areas. This buffer is intended to protect conservation areas and/or separate forestry operations (silviculture) from urban uses in order to reduce the conflicts between the uses, protect urban property values, and sustain forest industries.

Caveats
The TBL Tool draws on national data sets that meet federal mapping standards but may not align with the identified project boundaries or otherwise have limitations when applied at a local scale. Due diligence and field surveys are recommend to confirm the project location relative to sensitive natural resources. Known data limitations include the following:

• Digitized FEMA designated flood zones do not currently have full coverage. If the project is identified as being in or near a FEMA designated flood zone, the score is 0. If it is not, the score is NA, though this should be confirmed.
• The wetlands dataset does not cover Wisconsin and projects receive a NA score for this sub-measure. We recommend that the project location relative to wetlands be confirmed.
• The forestland data set does not cover Alaska or Hawaii and projects receive a NA score for this sub-measure. We recommend that project location relative to forestlands be confirmed.
• The prime farmland measure is based on soil quality and does not reflect whether the area is built up and, thus, may be appropriate for development at this time. The score in this version reflects that prime soils, even in an urbanized area, are a sensitive natural resource whose conservation should be considered.
• Coastal zones are a sensitive resource area, however, there is not a readily available mechanism to incorporate them into the TBL Tool at this time. Each state has its own coastal management zone. Activities that may impact the zone (environmentally, economically, or socially) may be subject to review by the state coastal zone management agency. Coastal zones and the areas subject to review for potential impact on coastal zones vary widely. There is not a database available that identifies location in or near a coastal zone. The TBL Tool could include a question related to CZM official review for potential impact and appropriate mitigation.
• The precision of these maps varies. For example, the National Research Council recently found that only 21% of the U.S. population has flood maps that meet all the federal data quality standards and in one study region floodplains identified by more accurate methods differed in shape by 20% from those identified by traditional techniques. In another example, the Water Bodies maps are compiled in the continental U.S. from 1:100,000 scale topographic sheets to meet National Map Accuracy Standards. For horizontal accuracy, this standard is met if at least 90 percent of points tested are within 0.02 inch (at map scale) of their true positions. At 1:100,000 scale, 0.02 inch is approximately 167 feet. The standard for other maps compiled at 1:24,000 scale is 40 feet. This is the scale most commonly used for soil survey maps, for example, which we used as a source for the Prime Farmland and Steep Slopes data.
In general, the locations of mapped features used in this project are only approximations. Therefore, the location of features based on these maps should be considered preliminary and should be supplemented with site surveys as appropriate prior to final project design and decision-making. Further, given that the estimate of impact is based on user-defined information (i.e., user draws map of project boundaries), care should be given to ensure that sensitive resources indeed are not impacted.

This measure addresses the presence of sensitive natural resources on the project site, not the estimated magnitude of impact. Careful review should be given if sensitive resources are identified in order to determine options for avoidance, mitigation, and enhancement.

Current challenges with respect to scoring are as follows:

- The precision of the data (maps and buffer zones) may lead to an inappropriately high score (i.e., sensitive area not identified when it does exist).
- The precision of the data may lead to an inappropriately low score (e.g., project is within a sensitive area mapping unit but is not impacting the sensitive area).
- The project is located in or near a sensitive natural resource but appropriate avoidance or mitigation will be in place such that the project should not receive a low score on this measure.

One alternative to address the shortcomings regarding this measure is to include follow-up questions for the TBL Tool user to note 1) whether the data has been confirmed and 2) type and magnitude of impact, including avoidance, mitigation, or restoration if applicable.

This measure is being carefully monitored during Beta testing.

Alternatives Considered

A number of alternatives have been considered for this measure, particularly with respect to scoring. For example, the Team considered assigning scores based on the percent of the project that is in a sensitive area. One issue with this method is that portions of the project area may be appropriate to a sensitive resource area (e.g., a nature preserve on part of a corporate campus). Another issue is that while the TBL Tool can identify the percent of a polygon that is in a sensitive area the eight sensitive resource areas cannot be summed as each draws upon a unique data set and there may be overlap (e.g., a polygon with 20% of the area identified as critical habitat and 20% identified as wetland does not necessarily have 40% of the area in sensitive resource areas as the critical habitat and wetlands areas may overlap partially or fully). Further, the amount of coverage (e.g., 20%) does not speak to the order of magnitude of the impact. For example, 20% of a 10 acre site (2 acres) is less than 20% of a 100 acre site (20 acres) so scoring would need to reflect total acres rather than percentages. However, total acres does not address the magnitude of impact, as some areas may be more sensitive (and less easily mitigated) than others.

As noted above, one alternative to address the shortcomings regarding this measure is to include follow-up questions for the TBL Tool user to note 1) whether the data has been confirmed and 2) type and magnitude of impact, including avoidance, mitigation, or restoration if applicable. A remaining question pertains to whether it is appropriate to differentiate the scores for farmland, forestland, and water bodies (currently scored at 50 versus 0, for presence of feature).
Performance Area: Green Operations

Why Does This Matter?
Facility operations and maintenance have significant impacts over the lifetime of a building. Green operations and management strategies that are well designed and implemented may yield lower operating costs, lower risk, and/or healthier and more comfortable working environments. While many of green design and construction measures contribute to these outcomes (e.g., energy efficient construction), this performance area considers activities specific to the on-going operations and maintenance associated with the project.

What Do We Want To Know?
• Are renewable resources contributing to the energy needs of the project?
• Is energy efficiency and conservation being employed to reduce the energy needs of the project?
• Are trip reduction strategies in place to reduce automobile dependence?
• Are tenants incentivized to adopt environmental stewardship in operations and maintenance?
• Does the project employ practices that produce better environmental outcomes than industry average?
• Do the products or services associated with the project contribute to a green economy?

What Measures Were Selected to Operationalize This Performance Area?
The Green Operations performance area measures are:
• Renewable energy
• Energy management
• Trip reduction strategies
• Tenant environmental incentives
• Lower than industry average water use
• Lower than industry average emissions use
• Industry best practices
• Green products and services.

The performance area score is calculated by averaging the project’s scores for the eight measures.

1. Energy from Renewable Resources

Energy supplies that come from renewable sources (e.g., biomass, wind, solar, hydropower and geothermal) can contribute to the triple bottom line by creating jobs, keeping dollars local, and providing lower environmental impact energy choices.

Measure Formula and Scoring
This measure considers whether a portion of the project’s energy will be derived from renewable energy sources. The measure score is calculated by averaging two sub-measure scores, as described below.

a) Project Renewable Energy Sources
A project earns 100 points if a portion of the project’s energy supply will be derived from renewable resources including solar, wind, geothermal, biogas, biomass, and low impact hydroelectric sources either through utility purchase, renewable energy certificates, or on-site generation sources AND the project will participate in the U.S. Green Power Partnership Program.
(http://www.epa.gov/greenpower/). The portion of green power is defined as 3-20%, depending upon the size of organization. Eligible green power sources include solar, wind, geothermal, biogas, eligible biomass, and eligible low impact hydroelectric sources. Commitments can meet with any combination of green power products (i.e., green power, renewable energy certificates, or on-site generation). A project earns 75 points if a portion of the project's energy supply will come from renewable energy resources but the project will not participate in the U.S. Green Power Partnership. No points are earned if no commitments to renewable energy will be made.

b) Tenant Incentives for Renewable Energy Sources

For projects with tenants, 100 points are earned if the owner will require tenants to participate in the U.S. Green Power Partnership Program, 75 points if the owner will incentivize tenants to participate in the U.S. Green Power Partnership Program, and 0 points if there will be no incentives or requirements to purchase energy from renewable sources. For projects without tenants, the sub-measure is not applicable and does not impact the project score.

Caveats

The scoring framework provides a mechanism to provide points for projects that employ renewable energy sources without participation in this program but assigns the highest score to participants in recognition of the higher degree of confirmation and yearly reporting required. The threshold for participation is low as the U.S. Green Power Partnership Program is a voluntary, no fee program.

2. Energy Management

Efficient use of energy resources can contribute to the triple bottom line by producing cost savings, conserving natural resources, and improving occupant comfort.

Measure Formula and Scoring

This measure considers whether an on-going strategy is in place to monitor and improve energy use. A project earns 100 points for participating in the Energy Star Energy Management Program, a no cost program that assists organizations to improve the energy performance of their facilities. A project does not earn points for this measure without participation in the Energy Star Energy Management Program. An option to claim the measure is not applicable is provided, however, an explanation must be provided. Information about the program can be found at http://www.energystar.gov/index.cfm?c=business.bus_commit.

3. Automobile Trip Reduction Strategies

Reductions in automobile trips associated with employee and/or customer commuting can improve air quality, while reducing fuel use and traffic congestions – all of which have significant human and financial costs. Further, active transportation options have the added benefit of improving health outcomes and reducing travel expenses.

Measure Formula and Scoring

This measure considers whether appropriate vehicle trip reduction strategies are in place. A project earns 100 points if strategies will be in place to reduce automobile trips associated with employee and/or customer commuting (e.g., telecommuting, transit passes, shuttles, bicycle facilities and locker rooms). Appropriate strategies will depend upon the location and type of industry and may include
options such as telecommuting, transit passes, shuttles, bicycle facilities and locker rooms. A project does not earn points for this measure if there will not be a trip reduction strategy in place.

**Caveats**
Evidence to support the claim should be made available. Consideration should be given to the quality of the strategy and the strength of implementation provisions.

### 4. Tenant Environmental Incentives

Building owners can encourage environmental stewardship in tenant operations and management in a number of ways. For example, lease incentives may be offered for things like reduced waste or green business certification, or occupancy agreements may establish protocols such as non-toxic cleaning and landscaping products. Incentives can be a powerful way to encourage preferred practices and may serve as an asset if the stewardship commitments differentiate the product in the marketplace.

**Measure Formula and Scoring**
For projects with tenants, 100 bonus points are earned if the owner will require, incentivize, or encourage tenants/occupants to meet best practices in green operations and management. For projects without tenants, this measure does not apply and the project score is not affected.

**Caveats**
Evidence to support the claim should be made available. Consideration should be given to the quality of the strategy and the strength of implementation provisions.

### 5. Water Use Lower than Industry Norms

Industrial processes that are designed to minimize water use may lower operating costs while conserving an essential non-renewable resource. Conservation can be particularly important in areas that are facing water shortages and/or in industries that have high water usage. This measure rewards excellence in water conserving design. The focus of this measure is on industrial processes (e.g., water recycling in chip manufacturing) rather than building features (e.g., low-flow bathroom appliances), which are addressed in the green building measure.

**Measure Formula and Scoring**
Projects may earn 100 bonus points if strategies will be implemented that lead to lower water use than is the norm for the industry. While any project can benefit from this measure, it may be particularly helpful to projects whose industry or industries were identified as higher than average water users in the industry eco-efficiency measure.

In some circumstances, JustMeans Insights may provide useful information to support analysis for this measure ([http://www.justmeans.com/blogs/Justmeans-Insights-Brings-Corporate-Soci---/1227.html](http://www.justmeans.com/blogs/Justmeans-Insights-Brings-Corporate-Soci---/1227.html)).

**Caveats**
Evidence to support the claim should be made available. Consideration should be given to the quality of the strategy and the strength of implementation provisions.
6. Emissions Lower than Industry Norms

Industrial processes that are designed to minimize toxic emissions to air, land, or water may benefit human health and maintain essential ecosystem services. Economic benefit may also accrue through reduced costs and/or the development of valuable new products and processes.

*Measure Formula and Scoring*
Projects may earn 100 bonus points if strategies are implemented that lead to lower than average emissions. While any project can benefit from this measure, it may be particularly helpful to projects whose industry or industries were identified as generating higher than average emissions in the industry eco-efficiency measure.

*Caveats*
Evidence to support the claim should be made available. Consideration should be given to the quality of the strategy and the strength of implementation provisions.

7. Industry Best Practices

A number of industries have developed certifications or best practices for environmental performance. When based on leading scientific evidence and stakeholder input, such standards can be an effective tool for improving industry performance.

*Measure Formula and Scoring*
Projects earn 100 bonus points if they demonstrate that the project will be compliant with best practices for their industry (e.g., forestry, information technology, tourism, sustainable agriculture and food production, infrastructure).

In some circumstances, JustMeans Insights may provide useful information to support analysis for this measure (http://www.justmeans.com/blogs/Justmeans-Insights-Brings-Corporate-Soci---/1227.html).

*Caveats*
Evidence to support the claim should be made available. Consideration should be given to the quality of the strategy and the strength of implementation provisions.

8. Green Products and Services

Goods and services that are designed to improve environmental quality, resource efficiency, and energy independence align job creation with natural resource stewardship in a unique way: not only are environmentally sensitive practices employed, the products themselves facilitate the transition to a more sustainable future.
Measure Formula and Scoring
Projects earn bonus points if some or all of the jobs created and/or retained pertain to one or more of the five green product and service categories defined by the U.S. Bureau of Labor Statistics (http://www.bls.gov/green/#definition). The project earns 100 bonus points if the percent of jobs pertaining to green goods or services is 76 to 100 and 75 bonus points if the percent of jobs is 1 to 75. The scoring system is designed to accommodate diversity of project scale (e.g., 50% of 10 jobs versus 10% of 500 jobs) and to ensure that the bonus points do not move a project out of the highest scoring quartile (i.e., 75 bonus points is the minimum). As this is a bonus point measure, projects that are not green job generators should not be and are not penalized.

Green products and services include:
- **Energy from renewable sources.** Electricity, heat, or fuel generated from renewable sources. These energy sources include wind, biomass, geothermal, solar, ocean, hydropower, and landfill gas and municipal solid waste.
- **Energy efficiency.** Products and services that improve energy efficiency. Included in this group are energy-efficient equipment, appliances, buildings, and vehicles, as well as products and services that improve the energy efficiency of buildings and the efficiency of energy storage and distribution, such as Smart Grid technologies.
- **Pollution reduction and removal, greenhouse gas reduction, and recycling and reuse.** These are products and services that:
  - Reduce or eliminate the creation or release of pollutants or toxic compounds, or remove pollutants or hazardous waste from the environment.
  - Reduce greenhouse gas emissions through methods other than renewable energy generation and energy efficiency, such as electricity generated from nuclear sources.
  - Reduce or eliminate the creation of waste materials; collect, reuse, remanufacture, recycle, or compost waste materials or wastewater.
- **Natural resources conservation.** Products and services that conserve natural resources. Included in this group are products and services related to organic agriculture and sustainable forestry; land management; soil, water, or wildlife conservation; and stormwater management.
- **Environmental compliance, education and training, and public awareness.** These are products and services that:
  - Enforce environmental regulations.
  - Provide education and training related to green technologies and practices.
  - Increase public awareness of environmental issues.

Caveats
Evidence to support the claim should be made available.

Alternatives Considered
Scoring this measure is a challenge because there is no threshold for a “good” or “bad” absolute or relative number of green jobs (e.g., a total of 10 jobs or 10% of overall jobs). Scoring by absolute number could disadvantage smaller projects and scoring by relative number could skew results (e.g., 90% of 10 jobs (9 jobs) may be inappropriately favored over 20% of 100 jobs (20 jobs). Further, there is no mechanism to account for order of magnitude of impact (e.g., how the green goods and services contributing to the environment and economy). The scoring framework rewards the projects with the largest percent of jobs categorized as related to green products and services, assuming that those projects likely to have a greater commitment and/or impact.
Goal: Community Well-being

Community well-being is both a goal and a facilitator of economic development. In the TBL Tool, the community well-being goal is comprised of three performance areas: place-making and accessibility, environmental health, and governance. An investment’s community well-being score is calculated by averaging its scores for these three performance areas, as described below.

The following information details why each performance area is important, the measures selected to operationalize the performance area, the measure formulas and scoring, and any data limits or caveats.

Performance Area: Place-making and Accessibility

Why Does This Matter?
Place-making creates inviting and distinctive spaces where people want to live, work and play. Place-making can contribute to the financial bottom line through increased property value, tourism receipts, and firm recruitment and retention. Accessibility helps ensure that residents and visitors can find the goods, services, and jobs they are looking for in ways that conserve energy and commuting costs, strengthen community fabric, and minimize pollution.

What Do We Want To Know?
• Are historic or cultural resources being created, conserved, enhanced, or lost?
• Are public spaces being created, enhanced, or diminished?
• How well is the site served by transportation choices (e.g., transit, walking, biking)?
• Does the project improve walkability, bikability, or transit access in the area?
• Does the investment create or retain jobs where there is high need?
• If applicable, are housing units affordable to a range of community residents?

What Measures Were Selected to Operationalize This Performance Area?
The Place-making and Accessibility performance area measures are:
• Cultural and historic resources
• Public spaces
• Walkability of project location
• Transit accessibility of project location
• Location in high need area
• No net loss of affordable housing
• Housing affordability
• Increase in walking, biking, or transit options.

The performance area score is calculated by averaging the project’s scores for the eight measures.

A bonus measure for contribution to community completeness and/or addition of key services or institutions (e.g., food and medical facilities) was considered as these features can contribute to economic development through direct impacts such as employment as well as indirect impacts such as worker and resident health and provision of services that can be important for attracting businesses and workers. However, this measure was not added because a) the distress measure captures the Health Resource and Services Administration Medically Underserved Areas (MUA) and U.S. Department of Agriculture (USDA) Economic Research Service (ERS) food deserts and b) facilities like libraries, civic
centers, schools, banks, and farmers’ markets can be addressed in the public space measure and/or increased walkability measure.

1. Cultural and Historic Resources

Preserving and enhancing cultural and historic resources can contribute to economic vitality through increased property value, tourism receipts, preservation of tradition-based economies, and firm recruitment and retention. In addition, community well-being may be improved if these resources contribute to civic pride, a sense of identity and connection, and well-utilized public spaces.

Measure Formula and Scoring
The score for this measure is calculated by taking the average of three sub-measure scores pertaining to historically or culturally significant practices, programming, and structures, facilities or districts, as detailed below.

a) Culturally or Historically Significant Structures, Facilities, or Districts

Historically or culturally significant structures, facilities, or districts can be important for place-based economic development, as well as for fostering community identity and pride.

Investments that preserve or enhance historically or culturally significant structures, facilities, or districts AND meet criteria for inclusion on national, state, or local registry and/or have a letter supporting cultural or historical significance provided by an appropriate historical or cultural commission or agency earn a score of 100. A score of 80 is earned if the investment will preserve or enhance historically or culturally significant structures, facilities, or districts but will not meet criteria for inclusion on national, state, or local registry and/or have a letter supporting cultural or historical significance provided by an appropriate historical or cultural commission or agency. Investments that will have a negative impact earn a zero score. If the proposed investment has no impact on culturally or historically significant structures, facilities, or districts then this sub-measure is not applicable and the project score is not affected.

Caveats
This measure does not address magnitude of impact. Evidence to support the claim should be made available.

b) Culturally or Historically Significant Practices

Historically or culturally significant practices include traditions, oldways, and unique culture of place. Conserving such practices can be important for place-based economic development, as well as for fostering community identity and pride.

This sub-measure is not applicable if the proposed investment has no impact on culturally or historically significant practices. Investments that have a positive impact earn the maximum score (100) and investments that have a negative impact earn the minimum score (0).
Caveats
This measure does not address magnitude of impact.
Evidence to support the claim should be made available. Consideration should be given to the quality of the strategy and the strength of implementation provisions.

c) Publicly Accessible Programming

Making historically and culturally significant resources accessible to a wide range of community members can contribute to a collective appreciation for heritage and context, and help individuals and communities to understand and interpret experiences.

If the proposed investment has no programming element such as performances or activities, this sub-measure is not applicable and the project score is not affected. Investments that include historically or culturally relevant programming earn 100 points if there is a component designed explicitly to serve the community (e.g., connection to schools, discount days). Investments that include programming but without any components designed to serve the community earn 50 points.

Caveats
This measure does not address magnitude of impact.
Evidence to support the claim should be made available. Consideration should be given to the quality of the strategy and the strength of implementation provisions.

2. Public Spaces

Well-designed and cared for public spaces are important to economic development because they can attract residents, workers, and visitors. They can add value in numerous ways, such as providing scenic beauty, recreational and gathering opportunities, and environmental benefit. Publicly accessible spaces take a variety of shapes and sizes, and may even be privately owned – from pocket parks and rooftop gardens, to plazas, scenic viewpoints, biking and walking trails.

Measure Formula and Scoring
If public space is not impacted (i.e., neither created, enhanced, or diminished) this measure does not apply and the project score is not affected. Investments that create or enhance public space AND have a plan in place to promote productive public use and care of the space earn 100 points (e.g., interpretive signs, marketing campaign, stewardship partnership with neighbors or schools, integration into the surrounding area, uses and activities are designed to create vibrancy and use across day and seasons). Investments that create or enhance public space without a plan to promote productive public use and care of the space earn 100 points. Investments that diminish quality, quantity, or access to public space earn 0 points.

Caveats
This measure does not address magnitude of impact.
Evidence to support the claim should be made available. Consideration should be given to the quality of the strategy and the strength of implementation provisions.
3. **Walkability**

A walkable location is one where people can access goods and services without driving. Walkability provides a number of potential benefits including lower commute expenses, improved air quality, active living, and vibrant streetscapes.

**Measure Formula and Scoring**

The score for this measure is the project location’s Walk Score – a number between 0 and 100 that is based on proximity to daily goods and services such as grocery stores, restaurants, shopping, coffee shops, banks, parks, schools, bookstores, and entertainment. Walk Score addresses proximity to amenities, but does not currently address quality of the walk (e.g., beauty, topography, safety, weather). If a project is located in an area that does not have a Walk Score, this measure is not applied and does not affect the project score. Investments that are designed to improve walkability can earn points in another measure.

The Walk Score algorithm awards points based on the distance to amenities in each category. Amenities within .25 miles receive maximum points and no points are awarded for amenities further than one mile. Categories include the following: grocery stores, restaurants, shopping, coffee shops, banks, parks, schools, bookstores, and entertainment. Walk Score uses a variety of data sources. Details of the methodology can be found at [http://www.walkscore.com/professional/methodology.php](http://www.walkscore.com/professional/methodology.php) and [http://www.walkscore.com/how-it-works.shtml](http://www.walkscore.com/how-it-works.shtml)

The project score for this measure is its Walk Score. To help contextualize the meaning of the score, Walk Score defines walkability as follows:

- **90–100** Walker’s Paradise — Daily errands do not require a car.
- **70–89** Very Walkable — Most errands can be accomplished on foot.
- **50–69** Somewhat Walkable — Some amenities within walking distance.
- **25–49** Car-Dependent — A few amenities within walking distance.
- **0–24** Car-Dependent — Almost all errands require a car.

**Caveats**

Walk Score is the best measure to date, though is not complete. Streetsmart is a stronger version but does not yet have as much coverage and is not available. Neither Walk Score nor Streetsmart reflects the quality of the walk (e.g., beauty, safety).

This measure does not speak to whether the investment is improving walkability. That is addressed in another measure.

4. **Transit Accessibility**

Transit accessible locations provide a number of potential benefits including lower commute expenses, improved air quality, and increased employment access – particularly for low-income populations.

**Measure Formula and Scoring**

The score for this measure is the project location’s Transit Score – a number between 0 and 100 that is based upon how well a location is served by public transit, with service defined by frequency, type, and distance to nearest stop. If a project is located in an area that does not have a Transit Score, this measure is not applied and does not affect the project score. Investments that are designed to improve transit accessibility can earn points in another measure.
Transit Score is defined and calculated as follows, per the WalkScore website (http://www.walkscore.com/transit-score-methodology.shtml):

**Transit Score** is a measure of how well a location is served by public transit. Transit Score is based on data released in a standard format by public transit agencies.

To calculate a Transit Score, we assign a "usefulness" value to nearby transit routes based on the frequency, type of route (rail, bus, etc.), and distance to the nearest stop on the route. The "usefulness" of all nearby routes is summed and we normalize this to a score between 0 – 100.

To calculate a raw Transit Score, we sum the value of all of the nearby routes. The value of a route is defined as the service level (frequency per week) multiplied by the mode weight (heavy/light rail is weighted 2X, ferry/cable car/other are 1.5X, and bus is 1X) multiplied by a distance penalty. The distance penalty calculates the distance to the nearest stop on a route and then uses the same distance decay function as the Walk Score algorithm. The weights reflect modes that have their own right of way (fewer delays, more reliability) and are associated with more real estate development (transit oriented development).

Since any measure of transit infrastructure (number of stops, number of weekly trips, etc.) will have its own unique range, it is necessary to normalize the raw Transit Score to generate a Transit Score from 0 to 100: 

\[ \text{transit\_score(location)} = \log(\text{raw\_transit\_score(location)}) \div \text{perfect\_score} \]

The amount of transit infrastructure can vary by several orders of magnitude. Scales for measuring things that have an extremely large range of normal values (sound volume, earthquake intensity, etc.) are typically logarithmic - a bus stop in a small town might see three trips a day, whereas downtown Manhattan might see tens of thousands. If Manhattan had a Transit Score of 100, then on a linear scale a small town's downtown might have a Transit Score of 0.01, whereas a logarithmic score might rate Manhattan as 100 and a small town as 10. The logarithmic score matches a rider's experience better: the added utility of one additional bus in a small town may exceed the addition of 10 new routes in downtown Manhattan.

In order to normalize from 0 to 100, we need to pick a "perfect score" location. To do this, we averaged the Transit Score of the center of a five U.S. cities where we had full transit data (San Francisco, Chicago, Boston, Portland, and Washington, D.C.) to create a canonical 100 Transit Score. Transit Score works in any city where the transit agencies publish data in the General Transit Feed Specification (GTFS) format (http://www.walkscore.com/transit-score.php):

The project score for this measure is its Transit Score. To help contextualize the meaning of a score, Transit Score defines its range as follows:

<table>
<thead>
<tr>
<th>Transit Score</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>90–100</td>
<td>Rider's Paradise — World-class public transportation.</td>
</tr>
<tr>
<td>70–89</td>
<td>Excellent Transit — Transit is convenient for most trips.</td>
</tr>
<tr>
<td>50–69</td>
<td>Good Transit — Many nearby public transportation options.</td>
</tr>
<tr>
<td>25 – 49</td>
<td>Some Transit — A few nearby public transportation options.</td>
</tr>
<tr>
<td>0 – 24</td>
<td>Minimal Transit — It is possible to get on a bus.</td>
</tr>
</tbody>
</table>

As noted above, the Transit Score methodology adjusts for scale (big city, small town) and, only provides a score where data is available.

*Caveat*
Coverage is not complete in all areas. Where data is unavailable, the project score for this measure is NA.
This measure considers whether the investment is made in a location that is accessible by transit. All other things being equal, investments made in places that have good transit access are preferred to investments made in places that do not. Investments that improve transit accessibility are addressed in another measure.

The score tells if a site is well served by transit but not what percentage of the population can get to the project in x time. For example, a recent report by the Brookings Institution indicates that a large portion of the population cannot access jobs by transit within a 90 minute one way commute (http://www.brookings.edu~/media/Files/Programs/Metro/jobs_transit/0512_jobs_transit.pdf). As this type of information becomes available this measure should be revisited (e.g., Transit Time Map is in Beta in four locations http://www.walkscore.com/transit-map.php).

**Alternatives Considered**

It would be useful to know whether and how the project contributes to or alleviates spatial mismatch or job-housing imbalance in the area. For example, considering the average project wage in relation to nearby housing prices would help determine whether an average worker could afford to live nearby. However, an easily accessible national data set is not available at this time so this alternative was not pursued. In addition, other factors influence housing location preference making accessibility of the site a preferred measure.

**5. Project Increases Walking, Biking, or Transit Options**

Locations that are easy to access by walking, bicycling, or transit may accrue significant financial, health and environmental benefits.

**Measure Formula and Scoring**

This measure considers whether the investment is designed to improve walkability, bikability, and/or transit accessibility (e.g., a mixed use development that contributes to community completeness, provision of retail services within ¼ mile of housing, or addition of transit or bike lane to area). Projects that are designed to increase walking, biking, or transit options earn 100 bonus points. If the project does not, this bonus measure does not apply and the project score is not affected.

**Caveats**

This measure does not address magnitude of impact. Evidence to support the claim should be made available. Consideration should be given to the quality of the strategy and the strength of implementation provisions.

**6. Location in High Need Area**

While jobs and wealth creation are important to all communities, the need is particularly great in areas that have experienced chronic disinvestment or economic disruption.

**Measure Formula and Scoring**

This measure considers whether the investment creates or retains jobs in areas with the greatest need. Investments that are located in a census tract designated as Severely Distressed receive 100 bonus points. The calculation is made based on the project address entered. Projects that are not located in a Severely Distressed area are not penalized, as this is a bonus measure.
Location in a high need area does not necessarily translate to employment for those in need. The TBL Tool’s career access and advancement measures consider whether the investment will serve traditionally disadvantaged and underutilized residents.

The U.S. Treasury Community Development Financial Institutions Fund (CDFI Fund) designates census tracts as “Severely Distressed” if they have:

- New Market Tax Credit (NMTC) Eligibility – includes tracts that have either (1) Median Family Income at or below 80% of Area Median Income (AMI) in 2000 or (2) Poverty Rate of 20% or greater in 2000
  
  **AND**

- Severe Distress using either Primary Criteria or Secondary Criteria, as described below.

  **Primary Criteria** is based on whether or not a given Census tract meets basic NMTC Eligibility, **plus one of the following factors:** having a median family income at or below 60% of AMI in 2000; having a poverty rate at or above 30% in 2000\(^9\); or having an unemployment rate of at least 1.5 times the national unemployment rate in 2000. Census tracts meeting the NMTC Primary Criteria for Severely Distressed Status are comparatively less in need as those Census tracts meeting the NMTC Secondary Criteria for Severely Distressed Status.

  **Secondary Criteria** is based on whether or not a given Census tract meets basic NMTC Eligibility, **plus two of the following factors:** meeting NMTC Heavy Distress requirements; being located within: an Small Business Administration Designated Historically Underutilized Business Zone (SBA HUB Zone), a CDFI Fund Hot Zone, a Medically Underserved Area (MUA), a Federal Empowerment Zone, Enterprise Community or Renewal Community, a High Migration Rural County, a Census tract within which a Brownfield is located, a HOPE VI Redevelopment Area, a Federal Native Area, an Appalachian Regional Commission or Delta Regional Authority Area, a Colonias Area, a State or Local Economic Zone, a FEMA Disaster Area, or a USDA-ERS Food Desert. Please note that the data do not take into account the following due to unavailability of data: HOPE VI Redevelopment Areas, Federal Native Areas, Colonias Areas, State or Local Economic Zones, and FEMA Disaster Areas.

Data Sources (Updating scheduled for Summer 2012):

- Census SF3 2000, HUD Income Limits 2000, Small Business Administration HUB Zones, CDFI Fund Census Download List, U.S. Department of Health and Human Services Health Resources and Services Administration Shortage Areas, HUD Renewal Communities, Empowerment Zones, and Enterprise Communities, Delta Regional Authority Distressed List, EPA Brownfields, ERS, USDA.

Poverty is based on Census 2000 SF 3 data. The Census 2000 SF3 uses the federal government’s official poverty definition. The Social Security Administration (SSA) developed the original poverty definition in 1964, which federal interagency committees subsequently revised in 1969 and 1980. The Office of Management and Budget’s (OMB’s) Directive 14 prescribes this definition as the official poverty measure for federal agencies to use in their statistical work. Area Median Income is based on HUD’s Income Limits in 2000. Unemployment is based on Census 2000 SF 3 data. The CDFI Fund added ERS/USDA Food Deserts in 2011 as one of the eligible secondary criteria for Severely Distressed.

\(^9\) The median family income threshold for NMTC, more specifically, is: Census tracts with, if located within a non-Metropolitan Area, median family income at or below 60% of statewide median family income or, if located within a Metropolitan Area, median family income at or below 60% of the greater of the statewide median family income or the Metropolitan Area median family income.
The CDFI Fund is updating the formula to replace many of the datasets, among them the Census 2000 SF3, with more current versions of the data. Scoring will draw upon these updated datasets when they are available.

**Caveats**

A short term limitation of using Severely Distressed indicators is that the data is from 2000, although that the formula will be updated soon. Because the NMTC criteria for Severely Distressed areas represent expectations by government agencies about projects that would result in economic development, the Severely Distressed indicators were deemed appropriate for defining areas of high-need.

Please note that the data do not take into account the following, due to unavailability of data: HOPE VI Redevelopment Areas, Federal Native Areas, Colonias Areas, State or Local Economic Zones, and FEMA Disaster Areas.

**Alternatives Considered**

Other options for defining areas of high need included the following:

- **U.S. Treasury CDFI Fund Priority Points**
  Beginning 2011, the CDFI Fund (U.S. Treasury) will rate applications based on the service county’s priority points. This Distress Indicator is based on poverty rates (2008 Census Bureau), median household income (2008 Census Bureau), unemployment rates (2008 Bureau of Labor Statistics), home foreclosures (2007 Housing and Urban Development), and high-cost mortgages (2007 Housing and Urban Development). Points ranging from 0 (lowest distress) to 5 (highest distress) are assigned to each county. CDFI Priority Points was not selected because a) some areas are not included and b) the indicator selected is more specific to location (census tract rather than county level).

- **High Unemployment Rate**
  The US Bureau of Labor Statistics (BLS) unemployment rate and BLS Alternative Measures of Labor Underutilization were seen as less precise measures of distress and slightly redundant to the career access and opportunity measures (i.e., does the project create employment access and opportunity).

- **US Economic Development Administration (EDA) Economic Distress indicator**
  The EDA Economic Distress indicator considers regional rather than census tract-level distress, and was deemed less suitable to the purpose of the TBL Tool.

7. **No Net Loss of Affordable Housing**

Affordable housing provides workers of various income levels and family members in various life stages options to remain in the community. When affordable housing units are lost, individuals and families lose the stabilizing foundation of home that is important to thrive. Further, displacement may lead to longer commutes and associated negative impacts such as pollution, less time for family and community, reduced competitive disadvantage.

**Measure Formula and Scoring**

This measure only applies to projects where restricted affordable housing units exist on the project site. Restricted affordable housing units are those whose affordability is legally designated and limited; for example, subsidized housing, tax credit housing, low-income housing, public housing, Section 8 housing, or deed restricted housing.
This measure considers whether the project will result in the loss of restricted affordable housing units. A project earns 100 points if there will be a binding agreement to provide one-for-one replacement of all currently affordable housing units, with first right of refusal granted to existing residents and in-perpetuity affordability covenants. The score is 75 if affordability restrictions are long term (e.g., 30+ years) rather than in perpetuity. The score is 25 if there will be one-for-one replacement of affordable housing units but with no affordability restrictions in place. If no agreements are in place to provide one-for-one replacement housing the score is 0.

A project providing one-for-one replacement (no net loss) of affordable housing units receives these points, regardless of whether the provision is required by local, state, or national law. Higher points are provided for projects that ensure long-term affordability of the units.

Caveats
This measure does not address magnitude of impact. Evidence to support the claim should be made available. Consideration should be given to the quality of the strategy and the strength of implementation provisions.

8. Housing Affordability

Housing costs are generally considered to be affordable when they do not exceed 30% of household income, though associated costs such as utility bills and transportation can significantly impact housing cost burden. An affordable housing supply is important for accommodating workers and families of various income levels and life stages. Housing affordability can impact recruitment and retention, as well as discretionary income to spend on local goods and services.

Measure Formula and Scoring
This measure considers whether new housing will include units that are affordable to households at or below 120% of Area Median Income (AMI) spending a maximum of 30% on housing costs. The measure only applies to projects that include housing in excess of one-for-one replacement of restricted affordable housing units. Scoring is based on percent of units made affordable (10% or more), eligibility (120% of AMI), and duration of affordability (e.g., in perpetuity, 30+ years).

A project that includes new housing units earns 100 points if there is a binding agreement ensuring that 10% or more of the housing units are affordable to households at or below 120% of Area Median Income (AMI) spending a maximum of 30% on housing costs, and that the affordability is assured in perpetuity through legal mechanisms such as recorded covenant or ground lease. The score is 75 if the affordability restrictions are long term (e.g., 30+ years) rather than in perpetuity. If less than 10% of the units are affordable to households with income at or below 120% of AMI then the measure score is 0.

A project providing affordable housing receives these points, regardless of whether the provision is required by state or local law. Higher points are provided for projects that ensure long-term affordability of the units.
Caveats
Evidence to support the claim should be made available.

This measure does not address magnitude of impact (e.g., number or percent of units, level of affordability).

Alternatives Considered
Definitions of low income and workforce vary by location and agency, generally based on area median income – Area Median Income (AMI). The U.S. Department of Housing and Urban Development (HUD) defines low income as follows: Extremely Low (30% of AMI), Very Low (50%) and Low (80%) (http://www.huduser.org/portal/datasets/il/il11/index.html). Moderate income is generally defined as 81% to 95% AMI and workforce housing is generally defined as 70 to 120% AMI.

An alternative method of scoring would be based on the percent of units made affordable (higher percent equals better score), the duration of affordability (longer restriction equals better score), and the fit between eligibility and community defined need (verify appropriate housing needs analysis).

Performance Area: Environmental Health

Why Does This Matter?
Job creation and retention strategies vary in their human health impacts. Industries that produce emissions known to negatively impact human health impose financial costs in the form of lost productivity and medical expenses, along with personal and social costs that cannot be monetized.

What Do We Want To Know?
• How well does the proposed investment support human health and safety?

What Measures Were Selected to Operationalize This Performance Area?
This performance area considers whether the jobs created and retained by an investment are in industries that produce relatively high levels of emissions known to have negative health effects. The score for this performance area is calculated by averaging the project’s scores on three measures: exposure to cancer toxics, exposure to non-cancer toxics, and exposure to criteria pollutants. As described below, two other measures were considered but not adopted: project location in relation to known environmental risks and health and safety performance of the proposed industry.

Measure Formula and Scoring

The environmental health impact per job created and retained is determined based on the industry or industries in which the jobs are located. The environmental impact associated with a sector is calculated taking a “cradle to gate” lifecycle approach which includes all of the impacts from upstream supply-chain processes that are inputs to the sector through to the point of sales to end-consumers (i.e., household consumers, business consumers, government consumers and exports). The impact calculations are based on environmental life cycle assessment (LCA) – a technique that accounts for the environmental impacts associated with a product (goods and services). Environmental impacts (stressors) include the natural resources consumed and pollutants emitted across the life of the product.

10 Portions of this text were contributed by Dr. Sangwon Suh, University of California at Santa Barbara and Industrial Ecology Research Service, LLC.
– from acquisition of raw materials, to manufacturing, use, and waste management (disposal, reuse, or recycling). “Cradle to grave” analyses consider impacts through product end of life (waste management), while “cradle to gate” analyses consider impacts through factory gate (manufacturing). Social life cycle assessment and life cycle costing are important emerging fields within LCA; however, our attention here is restricted to environmental impacts.

This measure helps identify whether the proposed project belongs to an industry that has greater or lesser environmental health impact per lifecycle job relative to other industries. This information can be useful for identifying potential issues and engaging with developers to design the project for best possible outcomes. At the same time, a project may belong to an industry that is low performing relative to other industries but is expected to have strong environmental performance relative to other projects in the same industry (e.g., the project belongs to a high emissions industry but will have innovative emissions reductions features). Projects with strong performance relative to their industry will be able to earn points for their leadership in the green operations performance area.

The following table displays the three measures for the environmental health performance area along with their unit of measure and potential environmental issues. Nine additional environmental impact categories (measures) are detailed in the Eco-efficiency Performance Area of the Natural Resource Stewardship Goal.

</table>

Scoring is determined by whether a project’s industry produces relatively more or less health impacting pollution per lifecycle job created. Because no standards exist for “environmental health impact per job created” (e.g., no amount of pollution per job or cancer per job that is designated as good or bad), the scoring is based on best and worst performers overall (e.g., relatively better or worse than other industries on a normalized 0 to 100 scale). Industries or sectors are defined using the North American Industry Classification System (NAICS) (http://www.census.gov/eos/www/naics/) – the standard for categorizing businesses by sector or industry. The NAICS level requested in the TBL Tool depends upon the amount of variation within an industry; more detailed information is requested only where differences among the types of companies within a given NAICS level are significant. For most industries, the user is asked to identify the three-digit level NAICS (retail and wholesale stop at the two-digit level, while a few others go one or two levels deeper). The TBL Tool user identifies the industry codes (NAICS) using a pull-down menu on the website. When a project includes multiple industries or NAICS, a weighted average is used. For example, if the project includes three NAICS that scored 50, 60,
and 80, and the project’s relative portion of jobs for each of those NAICS is 20%, 30%, and 50%, then the score would be computed as \((.20 \times 50) + (.30 \times 60) + (.50 \times 80) = 68\).

There are two main approaches to environmental LCA: “bottom up” LCA is based on site-specific information gathered across the life-cycle of a product, and “top-down” LCA is based on input-output tables that describe flows of goods and services between industries (sectors). The bottom-up (process-based) approach allows for precision and detail, but requires significant resources and can suffer from “truncation errors” associated with decisions regarding how far up the supply-chain to set boundaries for data inclusion. The top-down approach incorporates information about environmental stressors into industry input-output (I-O) tables, thus enabling analysis of environmental impacts at the sector level. Process-based LCA can misrepresent impacts by excluding important upstream processes, while I-O LCA can misrepresent impacts due to the coarseness of the data (i.e., if averages mask significant variation in a sector). However, while I-O LCA may not be suited to detailed comparisons at the product design level, it is generally suited to macro level policy decisions such as consideration of overall impacts of a system or comparing different options. By providing an indication of the relative environmental impact of various industries, IO-LCA provides valuable information to investors seeking to produce jobs with the least environmental impact.

The scores for this performance area are based on the Comprehensive Environmental Database Archive (CEDA) – an internationally recognized model that specifies environmental impact per dollar of final demand for each input-output (IO) sector. The Comprehensive Environmental Data Archive (CEDA) is an I-O LCA database that quantifies natural resource use and environmental emissions associated with a product’s life cycle. CEDA has been used by federal agencies such as the U.S. Department of Commerce and U.S. Environmental Protection Agency (EPA) and was determined to be an appropriate input-output life cycle analysis database for this application given its prior use by federal agencies and reputation for robustness and accuracy.

The Beta version of the TBL Tool was built with the CEDA 4 database, which uses the most detailed U.S. input-output table compiled by the Bureau of Economic Analysis (BEA) of the U.S. Department of Commerce (DOC) along with various environmental statistics and models. The results represent the national average cradle-to-gate environmental impact of each product distinguished in the input-output table. Cradle-to-gate is used synonymously with total (direct and indirect) environmental impact and includes impacts from all upstream supply-chain processes to the point of sales to end-consumers, i.e., household consumers, government consumers and exports.

CEDA 4 evaluates each I-O sector on thirteen different environmental impact categories following mostly the Tool for the Reduction and Assessment of Chemical and Other Environmental Impacts (TRACI) method developed and used by the U.S. EPA. The impact categories reflect best available science and societal consensus. Impact categories in Life Cycle Impact Assessment (LCIA) are developed through a step called “characterization,” which uses scientific findings to quantify the environmental impacts of various stressors to each environmental impact category, and to aggregate these into an equivalency of a single stressor, called a category indicator, for each impact category. The CEDA 4 impact categories and category indicators used for this performance area are presented above, along with a description of the potential environmental harm. References regarding the TRACI method can be found at the end of this section.
The input-output tables produced by the U.S. Department of Commerce Bureau of Economic Analysis (BEA) account for the flow of goods and services from industry to industry and to final users. The BEA I-O tables use an industry and product classification system derived from the North American Industry Classification System (NAICS). CEDA specifies environmental impact per dollar value of output for each input-output (I-O) sector (see Suh 2005 for details on how this is calculated). This includes both direct and lifecycle environmental impact information by IO sector. Direct impacts are those produced by the sector itself whereas lifecycle impacts include impacts from across the product life cycle. As noted above, CEDA 4 uses the TRACI method to define environmental impact per dollar value of output.

Environmental impact per dollar of output by I-O sector was converted to environmental impact per lifecycle job for each sector in order to meet the needs of the TBL Tool. Environmental impact per lifecycle job was computed by dividing total impact per I-O sector by the sector's total lifecycle employment. Lifecycle jobs includes all of the direct jobs associated with upstream supply-chain processes that are inputs to the sector through to the point of sale to end-users (i.e., household consumers, business consumers, government consumers, and exports). Data for lifecycle employment per I-O sector was derived from the November 2004 Bureau of Labor Statistics (BLS) Occupational Employment Statistics (OES), listed by 5-digit, 4-digit, 3-digit, and 2-digit North American Industry Classification System (NAICS) codes (http://www.bls.gov/oes/oes_dl.htm). Because the BLS employment statistics for agricultural sectors was highly aggregated, data from the 2002 U.S. Department of Agriculture (USDA) Census was used for sectors that had available USDA data (http://www.agcensus.usda.gov/Publications/2002/USVolume104.pdf). BLS and USDA do not provide employment data for every IO sector. In these instances, direct employment was estimated by dividing the total compensation for that industry (which is available for every IO sector) by the average annual wage of a more aggregated industry category (available from BLS). For example, if there was no employment data for industry category 212210 (Iron Ore Mining), but there was for 212200 (Metal Ore Mining), then employment was estimated as the total worker compensation for Iron Ore Mining divided by the average annual wage for Metal Ore Mining. If Metal Ore Mining had no employment data either, the average annual wage for industry category 212000 (Mining, Except Oil and Gas) would be used, and so forth. Several of the I-O sector codes are a combination of more than one NAICS code. If employment data was available for each component NAICS code, then that employment data was summed to give the total direct employment for the IO sector. If employment data was missing for any of the component NAICS codes, then employment was estimated using the method described above.

Caveats
Estimated impacts are limited to the data collected. Thus, while the data provide a good indication of relative environmental impact of various sectors, there is no consideration of impacts for which data is not collected (despite their potential significance). Also pertaining to significance of impact, while the results provide a sense of how sectors perform relative to each other, they do not provide a sense of performance with respect to a health or safety threshold (e.g., no thresholds are set for kilograms per job created so the data cannot be used for scoring based on a threshold beyond which a project is clearly problematic). Neither do they consider background conditions or simultaneous impacts and interactions. Input-Output Life Cycle Analysis (IO-LCA) provides valuable information regarding environmental impacts but is not a substitute for risk assessment.

---

11 Dollar value of output is defined as producers price = consumers price minus transportation margin and wholesale and retail margin.
Because the environmental data and USDA employment data was from 2002 and the BLS employment data was from 2004, sectors whose environmental impacts or employment have changed dramatically in the last decade may not be as accurately represented by the data. For the industries that have gone through rapid changes in terms of their production process, material intensity of production, environmental emission profiles and water and land use patterns since 2002, the result may not accurate reflect the current conditions. The Bureau of Economic Analysis (BEA) produces Benchmark survey input-output tables once every five years (http://www.bea.gov/). The tables for the 2002 base year were the most recent data available at the time the TBL Tool was constructed. If an industry’s position relative to others has changed significantly, the significantly this could impact scoring. Future versions of the TBL Tool should consider whether an investment should be made in updating the CEDA scores when more current information is available.

The environmental impacts are modeled based on U.S. average condition and, thus, provide a coarse estimate of industry impacts. Projects may be misrepresented by the CEDA results if their activities deviate substantially from industry averages, regional conditions are much different from the national average, or industry environmental impact or employment have changed dramatically relative to other industries since the CEDA data was compiled. Consequently, the data produced for these measures should be viewed as rough estimates that provide guidance on the likely impact of a project relative to projects in other sectors. Where appropriate, more detailed project specific environmental assessments should be conducted.

Alternatives Considered
Workers and residents of the proposed project may be exposed to toxins attributable to the location (site) of the project. The U.S. Environmental Protection Agency (EPA) maintains a database of exposure to a variety of pollutants (http://www.epa.gov/enviro/). These include, for example, superfund sites and facilities that use or release toxic chemicals. However, it is not feasible to map the proposed project in relation to EPA regulated facilities because the EPA database is constantly being updated and, thus, the TBL Tool information would be quickly out of date (http://iaspub.epa.gov/enviro/data_update_v2). We suggest that the environmental risks associated with the site be considered.

A measure to consider whether the investment is in an industry with higher than average expected rates of injury and illness was considered. In 2010, the U.S. Bureau of Labor Statistics estimated a total of 4,547 fatal work injuries (3.5 per 100,000 employees) and 3.2 million nonfatal injuries and illnesses. The impact of these injuries includes direct economic costs to workers (e.g. loss of earnings) and employers (e.g. payment of worker compensation benefits, loss of productivity and competitiveness) as well as social consequences of the effects on quality of life (e.g., family stress). Additionally, employer costs of occupational accidents include costs to hire and train replacement workers, lower productivity of coworkers, and administrative expenses. The Bureau of Labor Statistics (BLS) maintains data regarding worker safety by NAICS (http://bls.gov/iif/), however, the information is not well-suited to the TBL Tool because a) six digit level NAICS information would be required and many TBL Tool users are unlikely to have that level of detail for their project and b) the industries identified as “worse performers” include agriculture, health care, civil engineering construction, skiing, police and fire protection and it would be inappropriate to suggest that these industries be avoided or that they contribute to a weak bottom line.

The National Institute of Building Sciences Whole Building Design Guide includes security and safety objectives. Information to support occupant health and safety can be found at: http://www.wbdg.org/design/ensure_health.php.
Environmental Input Output Lifecycle Analysis is an efficient method for estimating the direct and total environmental impacts associated with economic development without conducting detailed project specific environmental studies. CEDA is not the only database capable of supporting this approach, but it was deemed to be the most complete and accessible for this project.

Additional Information
Resources regarding life cycle assessment, TRACI, and CEDA can be found above in the Eco-efficiency Performance Area section.

Performance Area: Governance

Why Does This Matter?
Governance or management systems that are fiscally responsible, accountable, and inclusive of relevant stakeholders contribute to triple bottom line performance. These strategies help to ensure that investments do not diminish service levels and quality of life, incentive agreements are fulfilled, and investments are supported by and well-suited to the community.

What Do We Want To Know?
• Have stakeholders been appropriately engaged?
• Is there sufficient capacity of key infrastructure to serve the proposed project?
• Are accountability mechanisms in place?
• Are jobs being created in one locality at the avoidable expense of another?
• Will existing residents or businesses be relocated or displaced and, if so, what measures are being taken to minimize negative impacts?

What Measures Were Selected to Operationalize This Performance Area?
The Governance performance area measures are:
• Stakeholder engagement
• Key infrastructure capacity
• Accountability mechanisms
• Anti-poaching
• Relocation planning and collaboration
• Prevention and mitigation of displacement.

The score for this performance area is calculated by taking the project’s average score for the six measures. Fiscal impact is considered in the economic vitality section of the TBL Tool.

1. Stakeholder Engagement

Appropriate stakeholder engagement can help ensure that important information is taken into account in the project design and that the project is well suited to the community. Appropriate stakeholder engagement may also broaden project support, which can be essential for project viability and important for maintaining community cohesion.

Engagement can take a range of forms including informing (I’m letting you know/I’m keeping you posted), consulting (I’m asking you), collaborating (I’m working with you), and resolving (we’re working
Determining what types of engagement are most appropriate for a given project depends upon contextual issues such as project type, likely impacts, past events, and stakeholder characteristics.

While engagement may be used for different purposes and take different forms, there are overarching principles of effective engagement that can be applied to most situations. These include defining individuals and organizations that may be affected by or who can affect the project, establishing clear expectations regarding the engagement process, following through in a timely manner, selecting the right format for the engagement objectives, and being honest and accountable. Stakeholders may include agencies, funders, developers, users, adjacent neighborhoods or jurisdictions, and specific populations or groups. Appropriate engagement strategies may range from newsletters to town halls to social media, and may include translation, childcare, transit assistance, or culturally sensitive meeting spaces.

When considering what engagement strategy best fits the circumstances it is helpful to consider such issues as level of controversy, significance of the decision, cultural norms (e.g., it may be appropriate to approach a community elder first, or meet in certain locations), and capacity (e.g., skills and time). It is also important to consider and help balance power differentials that may inhibit fair outcomes.

This measure considers whether diverse stakeholders have been appropriately engaged in project development and, for rating systems, whether they support the proposed project.

**Measure Formula and Scoring**
This measure considers whether there is a commitment to 1) identify and work with diverse stakeholders that may affect or be affected by the project in order to 2) develop and implement an appropriate engagement strategy that includes tasks, timelines, and responsibilities. An appropriate engagement strategy will depend upon the context, and diverse stakeholders may include people of different age, ethnicity, or income as well as different agencies, jurisdictions, disciplines, and businesses. A score of 100 is earned if there will be a program or policy to identify and work with diverse stakeholders that may affect or be affected by the project in order to develop and implement an appropriate engagement strategy that includes tasks, timelines, and responsibilities. A score of 0 is earned if a program or policy will not be in place.

**Caveats**
Evidence to support the claim should be made available. Consideration should be given to the quality of the strategy and the strength of implementation provisions.

### 2. Key Infrastructure Capacity

Sufficient capacity for key infrastructure such as water, sewer, transportation, and utilities must be in place to maintain competitiveness and quality of life. This measure considers whether the capacity of key infrastructure to serve the project has been confirmed and the levels are adequate.

**Measure Formula and Scoring**
Sufficient capacity is defined as service levels for the intended use (e.g., ten ton road to service the project), rather than overall indirect or induced use. Indirect or induced demand should be addressed in the fiscal impact and stakeholder engagement measures in order to ensure that fiscal resources are not strained, levels of service do not decline, and quality of life is not diminished (including school impacts if appropriate).
The measure score is 100 if existing infrastructure capacity has been evaluated and is or will be sufficient to accommodate the proposed project without exceeding adopted or appropriate level of service standards. The measure score is 0 if capacity has not been confirmed or if capacity has been evaluated and is not sufficient to serve the project without exceeding adopted or appropriate level of service standards.

The following template may be useful for securing agency input regarding key infrastructure capacity:

The following serves to note that the [Jurisdiction, Agency] [e.g., City of Midvale Department of Engineering] has identified adequate sewer capacity to handle the [Name of Project] at the estimated capacity of [e.g., gallons per day]. This communication in no way serves as an endorsement or approval regarding the proposed project. Rather, it provides confirmation that infrastructure capacity has been considered and appears to sufficient to serve the proposed project.

Alternatives
This measure relies on user-defined information as there is no readily available national source of data regarding infrastructure capacity.

Caveats
Evidence to support the claim should be made available.

3. Accountability Mechanisms in Place

Accountability mechanisms are useful for ensuring that investments align with priorities, commitments are fulfilled, and investment dollars are accounted for.

Measure Formula and Scoring
The score for this measure is calculated by averaging the project’s scores on four sub-measures, as defined below: incentives linked to performance, transparency of public funding, responsible contracting, triple bottom line business certification.

a) Incentives Linked to Performance
Incentives are often provided in exchange for commitments to specific deliverables such as job creation. Linking incentives to performance is an important component of fiscal responsibility and accountability.

This measure only applies when incentives or payments apply to the proposed investment. The sub-measure score is 100 if legally binding provisions are in place to verify performance and withhold, recapture, or recalibrate incentives if performance goals are not met. The sub-measure score is 0 if no legally binding accountability provisions for incentives or payments are in place.

Caveats
Evidence to support the claim should be made available. Consideration should be given to the quality of the strategy and the strength of implementation provisions.
b) Transparency of Public Funding
The use of public funds should be transparent with respect to key details such as funding amounts, recipients, agreements, conditions, risks, and performance. To be useful, this information needs to be easily accessible to the public (e.g., available on-line).

This measure only applies if the project will be receiving public funds. The score earned for this sub-measure is 100 if subsidy and performance information is easily accessible to the public and 0 if subsidy and performance information is not easily accessible to the public.

Caveats
Evidence to support the claim should be made available. Consideration should be given to the quality of the strategy and the strength of implementation provisions.

c) Responsible Contracting
Responsible contractor programs establish basic requirements that a contractor must meet in order to be eligible to bid on a project. Responsible Contractor Standards (RCSs) may focus narrowly on past performance (e.g., prior violations of law, project completion) or inclusively to address criteria such as project wages and benefits for workers. Well-designed comprehensive responsible contractor standards are useful for ensuring that investment dollars are stewarded and maximum value achieved.

The score for this sub-measure is 100 if the project will have responsible contractor standards specifying the basic requirements that a contractor must meet in order to be eligible to bid on work associated with the investment. At a minimum the standards should address quality, history, and performance. Wages and benefits may be addressed in the quality construction jobs measure. The score for this sub-measure is 0 if no responsible contractor standards are defined. If the project does not include construction, the measure does not apply.

Caveats
Evidence to support the claim should be made available. Consideration should be given to the quality of the strategy and the strength of implementation provisions.

d) Triple Bottom Line Business
Businesses that have received third party certification of their sustainability performance demonstrate strong alignment with TBL goals and deserve recognition for their commitments.

B Corporations are businesses that have obtained third party certification regarding social and environmental performance by B Lab, a non-profit organization (http://www.bcorporation.net/). While a number of reporting systems exist to help businesses and their stakeholders assess sustainability issues, to date there is not an alternative third party certifier of triple bottom line businesses. This measure can be adjusted to accommodate additional certifications in the future if appropriate.

If the applicant is a certified B Corporation and/or provides incentives that favor B certified companies as tenants or project beneficiaries 100 bonus points are earned. The sub-measure is a bonus and is not included in the project score if there is no certification.

Caveats
Evidence to support the claim should be made available.
4. Anti-Poaching

Economic development that is based on recruitment and relocation of existing businesses may generate jobs in one community while leaving another worse off. In some cases, relocation may be occurring because a facility has exceeded its capacity, needs an upgrade, or requires a workforce with different skills. In these circumstances, efforts should be made to meet these needs without dislocating jobs in the current location if feasible and/or mitigate negative impacts on the existing community.

This measure considers whether the jobs “created” by this project are the result of avoidable job loss in another jurisdiction. If the project does not involve relocation of an existing business from another location, this measure does not apply and the project score is unaffected. A neutral score (NA) is earned if the project involves the relocation of an existing business but the jurisdiction gaining the jobs cooperates with the jurisdiction losing the jobs to try and keep the company in the existing jurisdiction and/or to mitigate impacts on the existing jurisdiction. Documentation should address why the jobs need to be relocated, expected impacts on the communities losing the jobs, and efforts to avoid or mitigate impacts on the communities losing jobs. A score of 0 is earned if the project provides incentives or otherwise encourages the relocation of existing jobs from another jurisdiction.

Caveats
Evidence to support the claim should be made available. Consideration should be given to the quality of the strategy and the strength of implementation provisions.

5. Relocation Planning and Collaboration

Businesses or residents that are temporarily or permanently relocated due to an investment may experience higher rents, longer or more expensive commutes, and a loss of important community ties. Impacts of relocation to existing residents and businesses must be carefully considered and appropriate plans made to ensure that relocation does not negatively affect this population. Further, because the burdens of relocation often accrue disproportionately to disadvantaged and underrepresented populations, focused attention needs to be given to these residents and businesses.

Measure Formula and Scoring
This measure applies if temporary or permanent relocation will occur as part of this project. The measure score is calculated by averaging the two sub-measures scores described below. The maximum measure score of 100 is earned when a relocation plan appropriate to the needs and interests of existing residents and businesses is developed with meaningful engagement of the affected parties. A measure score of 50 is earned when a reasonable relocation plan is developed but without meaningful engagement of affected parties. Zero points are earned if an appropriate relocation plan is not created. This measure does not apply if there is no temporary or permanent relocation of residents or businesses associated with the investment.

a) Resident and/or Business Relocation
This question is for informational purposes and identifies whether any residents and/or businesses will be temporarily or permanently relocated as part of the project. This sub-measure has no scoring.
b) Relocation Plan Appropriate to the Needs of Existing Residents and Businesses
This sub-measure considers whether a relocation plan appropriate to the needs and interests of residents and businesses before, during, and after relocation will be developed. Details of the relocation plan may include counseling and support services, financial assistance to navigate the costs associated with relocation, opportunities to return, and clear specification of tasks, timelines, responsibilities, performance monitoring, and recourse/consequence. If a relocation plan appropriate to the needs and interests of the community will be in place, the score is 100. If a relocation plan appropriate to the needs and interests of the community will not be in place the score is 0. This measure does not apply if residents and/or businesses will not be temporarily or permanently relocated as part of the project.

c) Collaboration to Create Relocation Plan
This sub-measure considers how the affected businesses and/or residents are involved in the development of the relocation plan. If there is or will be a plan to meaningfully engage diverse residents and businesses in the area in creating the relocation plan, with a particular focus on underrepresented and disadvantaged populations, the sub-measure score is 100. If a meaningful plan is not in place, the score is 0. This sub-measure is not applied if residents and/or businesses will not be temporarily or permanently relocated as part of the project.

Caveats
Evidence to support the claim should be made available. Consideration should be given to the quality of the strategy and the strength of implementation provisions.

6. Prevention and Mitigation of Displacement

Voluntary displacement occurs when individuals or business choose to move from the project area because they perceive that the move will leave them better off. Involuntary or indirect displacement occurs when residents or business move because they can no longer afford to stay in the area. This type of dislocation is similar to the displacement that occurs when residents and businesses are temporarily or permanently relocated as part of the site development and construction, though there are differences in cause and remedy.

Displacement can weaken the triple bottom line in a number of ways. For example, residents and businesses that are displaced may experience higher rents, longer or more expensive commutes, and a loss of important community ties. The potential for involuntary or indirect displacement of existing residents and businesses in the project area must be carefully considered and appropriate prevention and mitigation plans implemented.

Measure Formula and Scoring
This measure applies if the cost of living or doing business in the neighborhood surrounding the project is likely to increase as a result of this project. The measure score is calculated by taking the average of the two sub-measure scores described below. The maximum score of 100 is earned when affected parties collaborate to create a strategy to prevent and mitigate potential displacement due to factors such as rising rents and taxes. A score of 50 is earned when an anti-displacement strategy is developed but without meaningful engagement of affected parties. Zero points are earned if an anti-displacement strategy is not created. This measure does not apply if residents and/or businesses are not likely to be priced out of the neighborhood or involuntary displace due to the project.
a) Cost of Living or Doing Business
This question is for informational purposes and identifies whether the cost of living or doing business in the neighborhood is likely to increase as a result of this project leading to residents and/or businesses being involuntarily or indirectly displaced. This sub-measure has no scoring.

b) Anti-displacement Strategy
This sub-measure considers whether an anti-displacement strategy appropriate to the needs and interests of residents and businesses will be developed. The strategy could include things like assistance with purchasing units, affordability agreements, tax relief, and counseling and skill-building to identify and successfully pursue suitable options. If an appropriate anti-displacement strategy will be in place, the sub-measure score is 100. If an anti-displacement strategy appropriate to the needs and interests of the community will not be in place, the score is zero. This sub-measure is not applied if the project is not expected to contribute to involuntary or indirect displacement.

c) Anti-displacement Strategy Collaboration
This sub-measure considers whether there is a plan to meaningfully engage diverse residents and businesses in the area in creating the anti-displacement strategy, with a particular focus on underrepresented and disadvantaged populations. If a plan will be in place, the sub-measure score is 100. If an anti-displacement strategy appropriate to the needs and interests of the community will not be in place, then the score is zero. This sub-measure is not applied if the project is not expected to contribute to involuntary or indirect displacement.

Caveat
Evidence to support the claim should be made available. Consideration should be given to the quality of the strategy and the strength of implementation provisions.
Appendix One: National Advisors

We would like to express our gratitude to the numerous individuals from across the U.S. who provided valuable insights and suggestions regarding the TBL Tool. In addition, we would like to acknowledge the extra effort and contribution made by the following individuals, most of whom participated in a two-day work session held in October, 2011 to finalize the TBL Tool measures and design parameters. The following represents our expression of thanks and does not imply an endorsement of the TBL Tool by these individuals or their organizations.

- Richard Berndt - EDA Seattle Office, Regional EDR
- Keith Bisson – Coastal Enterprises, Inc., Director Northern Heritage Development Fund
- Darrell Brown – School of Business, Portland State University, Professor of Accounting
- Matt Chase – National Association of Regional Development Organizations, Executive Director
- Abe Farkas – ECONorthwest, Development Services Director
- Dan Gundersen – Baltimore County Maryland Economic Development Department, Executive Director; IEDC Board Member
- Darrene Hackler – George Mason University, Professor of Government and Politics
- Megan Henderson – Heart of Texas Council of Government, Director of Regional Services
- Terry Holzheimer – City of Arlington, Virginia Economic Development, Director
- Cheryal Lee Hills – Minnesota Region Five Development Commission, Executive Director
- Chris Hoene – National League of Cities, Director of Research and Innovation
- Betty Huskins – North Carolina Association of Regional Councils of Government, Executive Director
- Marcy Jaffe – MJC, Director
- Mike Krajovic – Fay-Penn Economic Development Council, President and CEO
- Deb Markley – Rural Policy Research Institute, Managing Director RUPRI Center for Rural Entrepreneurship
- Lang Marsh – National Policy Consensus Institute, Fellow
- Kathy Nothstine – National Association of Regional Development Organizations, Program Manager
- David Porter – EDA Portland Office, Economic Development Representative
- John Provo – Virginia Tech Office of Economic Development, Director
- Colin Rowan – Principal, United Fund Advisors
- Vivek Shandas – School of Urban Studies and Planning, Professor, Portland State University
- Liz Thorstensen – International Economic Development Council, VP Knowledge Management & Economic Development Practice
- Adam Zimmerman – Craft3, Senior Vice President
Appendix Two: Review of Tools, Literature, and Community Priorities

As described earlier, our approach to developing the TBL Tool was rigorous, inclusive, transparent, and pragmatic. The TBL Tool is informed by community-identified priorities, leading edge practice, current research, and end-user feedback.

Our three-pronged approach to defining triple bottom line economic development is detailed below. The findings from this research are included in our companion report, TBL Economic Development: Assessing Current Practice and Theory.

1. Review of TBL Assessment Tools

Tools that are designed to assess the triple bottom line vary based on their purpose (e.g., assess, evaluate), focus (e.g., business, real estate, infrastructure), and approach (e.g., impact, targets, alignment). Our search for TBL assessment tools builds upon prior work and includes a review of the literature, web based search, and a survey of economic development professionals (see below).

---

12 The term tool, framework, and process are used interchangeably in the literature.

Very few tools have been identified that specifically address economic development, though there are a
number of tools that address regeneration development or infrastructure – which are often part of ED
efforts. Tools reviewed include:

2. Review of Literature

We reviewed the literature on triple bottom line economic development to identify core elements, as well as examples of projects or assessment processes. The databases searched include:

- **Academic Search Premier** - Academic Search Complete, Business Source Premier, E-Journals, EconLit, GreenFILE, Military and Government Collection, Regional Business News
- **ULI Development Case Studies**
- **PAIS** - Conference Papers Index, EIS, Environmental Sciences and Pollution Management
- **Google Scholar**

We systematically considered more than 50 search term combinations in our review of academic and gray literature. The search term combinations included:

<table>
<thead>
<tr>
<th>One ‘A’ Term</th>
<th>Twelve ‘B’ Terms</th>
<th>Seven ‘C’ Terms</th>
</tr>
</thead>
<tbody>
<tr>
<td>economic development</td>
<td>sustain*</td>
<td>business incubator</td>
</tr>
<tr>
<td>triple bottom line</td>
<td>business park</td>
<td></td>
</tr>
<tr>
<td>community impact</td>
<td>industrial park</td>

<td>retail</td>
<td></td>
</tr>
<tr>
<td></td>
<td>tourism</td>
<td></td>
</tr>
</tbody>
</table>

Where further narrowing was necessary (e.g., more than 500 “hits” for a search term combination), the search was narrowed by year of publication (1990, 1995, or 2000 depending on the amount of narrowing required). Our review stopped at 500 for any given search term combination.  

3. Review of Comprehensive Community Indicator Programs

To ensure that the TBL Tool aligns with community priorities, we reviewed a sample of community-defined goals from across the six EDA regions. Comprehensive indicator programs were selected as the unit of analysis because they address the broad range of priorities held by a jurisdiction and have been identified as relevant to economic development.

The indicator programs reviewed were identified by searching the Community Indicators Consortium website, as well as literature and websites on the topic. We sought to identify at least one comprehensive indicator program at the municipal, county or region, and state level for each EDA region. We selected programs of regional and rural-urban diversity in order to determine whether core community priorities can be identified across context and, if so, what those are. The community indicator programs reviewed include the following:

14 Our review in Google Scholar included the following search term combinations: sustainab* + “economic development” + checklist; sustainab* + “economic development” + assess + tool; “economic development” + “triple bottom line” + assess + tool; “economic development” + “triple bottom line” + checklist; infrastructure + sustainability + assess + tool; infrastructure + sustainability + assess + checklist; infrastructure + “triple bottom line” + assess + tool; infrastructure + “triple bottom line” + checklist; multi-criteria + decision + support; multi-criteria + assess* + sustain*; multi-criteria + “triple bottom line” + assess*. The first ~100 “hits” per search term combination were reviewed for relevance.

16 The Community Indicators Consortium (http://www.communityindicators.net/) is an online network of worldwide community indicator practices. An online database provides general information and links to current indicator projects.

17 Inter-state or intra-state.

While comprehensive indicator programs vary in their formats, terms, emphases, and applications, there are some common structural elements. Typically, an indicator program defines headline categories or themes and indicators are clustered in those categories, often as part of a sub-category. Our review was designed to identify core themes – the visions, goals, or objectives a community cares about. These findings help inform the types of community impacts to consider when assessing potential economic development investments.

Our review indicates that communities large and small, rural and urban, have many of the same aspirations. All thirty-one of the indicator programs have goals pertaining to the natural environment, transportation and mobility, human health and safety, economic vitality, and education. Twenty-one of the jurisdictions have goals around housing, and half of the jurisdictions have articulated priorities regarding the built environment. Civic engagement, good governance, arts and culture, and diversity or inclusion are addressed by approximately one-third of the indicator programs.
This review is indicative and not conclusive, and does not reflect the quality of the indicator programs. What it does tell us is whether jurisdictions with comprehensive indicator programs articulate common community goals and, if so, what those are.

The common goals identified are consistent with literature regarding factors supportive of economic development (e.g., educated workforce, quality place to live). The TBL Tool can help communities make more strategic investments by better aligning economic development investments with community priorities.
Appendix Three: Alignment with Current EDA Application Requirements

The TBL Tool aligns with current EDA 900 application requirements as follows:

A3 CEDS – Tool asks whether project aligns with regional economic development strategy.
A8 budget – Tool asks for total project costs.
A9 leverage – Tool calculates leveraged dollars.
A13.3 distress – Tool identifies high need areas, though uses a different measure.
A13.5 Beneficiaries – Tool identifies industry by NAICS, jobs created and retained.
M.1- some fit with metropolitan review in question regarding adequate capacity of key infrastructure.
M.6. Operation and maintenance measure would provide some information that may be helpful here as well as fit with strategic priorities.
M.7 Tool has question regarding relocation and displacement
M.8 Environmental Requirements Tool identifies presence of eight sensitive natural resources on site and proximity to TRI facility. Also requests information on historic and cultural features and notes if project involves remediation.

Environmental Narrative
The TBL Tool will help determine if an environmental narrative is warranted. That is, it identifies whether the project is located in area that has wetlands, floodplains, critical habitat, protected areas, endangered species, and identifies whether the industry has higher than average waste, toxics, and water use. The TBL Tool also identifies whether adequate water and sewer capacity is in place to serve the project, and whether historic and cultural resources are impacted. These are all items on the environmental narrative form. Focus group participants noted that it would be valuable to have a tool that helps them identify this information.

Non-attainment is not included at this time because that data is at a county level. We could add that to the TBL Tool as an FYI item (not part of score) and this would tell the reviewer whether extra scrutiny may be warranted.

For a rating version of the TBL Tool, if an environmental narrative is produced, the information from the narrative will be useful for completing a number of TBL Tool measures (e.g., any avoidance or mitigation where sensitive lands have been identified).
